Summary

IRC (Internet Relay Chat) is a text-based chat system for [instant messaging](#). IRC is designed for [group communication](#) in discussion forums, called [channels](#), but also allows one-on-one communication via [private messages](#)... .

Internet Relay Chat is implemented as an [application layer](#) protocol to facilitate communication in the form of text. The chat process works on a [client-server networking model](#). Users connect, using a client—which may be a [web app](#), a [standalone desktop program](#), or embedded into part of a larger program—to an IRC server, which may be part of a larger IRC network. Examples of ways used to connect include the programs [Mibbit](#), [Kiwirc](#), [mIRC](#) and the paid service [IRCCloud](#).

From the Wikipedia entry on IRC, at <https://en.wikipedia.org/wiki/IRC>

MERK is a free and open source Internet Relay Chat client for Windows and Linux. It uses a "multiple document interface", in which the application works as a parent window that contains other windows for servers, channels, and private chats. The popular Windows shareware client mIRC is an example of another IRC client that uses a multiple document interface.

MERK is written in the Python programming language, using the PyQt library for the graphical interface and the Twisted library for networking. MERK also comes bundled with four other open source libraries:

- **qt5reactor**, for getting PyQt and Twisted to work together
- **pyspellchecker**, which provides the spellchecking mechanism
- **emoji**, providing support for emoji shortcodes
- **pike**, providing support for plugins

MERK has a scripting engine allowing most functionality to be automated. The core concept of the scripting engine is the [context](#): a context is a window, either a [channel](#), [private chat](#), or [server](#) window, that the [commands](#) executed are intended to interact with. Scripts can be [executed on connection](#), or [executed from text input](#). MERK comes with a [script editor](#) with features to make writing scripts easy and fun, with no prior programming experience required.

MERK's [plugin system](#) allows users to extend MERK's capabilities with Python, no matter what platform they're running.

As IRC is a text-based protocol, MERK features a rich text display, which can be [easily configured](#). MERK supports the display of mIRC colors¹, which can optionally be stripped from messages.

¹ <https://en.wikichip.org/wiki/irc/colors>

Running MERK

MERK comes in two different versions: the Python version, which uses the Python interpreter to run MERK, and a PyInstaller version of MERK, which runs on Windows, and doesn't require the Python interpreter. Both versions behave exactly the same way, and have only minor differences.

PyInstaller Version

Download the Windows version of MERK, and unzip the archive to anywhere you'd like. The archive contains a folder named **lib**, the **merk.exe** executable, and **README.html**. Just double click **merk.exe**, to run MERK. That's it!

There's also an installer for MERK. Download the Windows installer version and unzip the archive to wherever you'd like. Double click on **setup.exe**, which will guide you through installing MERK on your computer. MERK can be installed wherever you'd like, and can either be installed for a single user, or for all users on your computer.

Python Version

MERK requires several libraries to be installed in order to run: **Python 3.9+**, **PyQt**, **Twisted**, and if you'd like to connect to servers via SSL/TLS, **PyOpenSSL** and **service_identity**. If you're running MERK on Windows, you may also need **pywin32**. All of these libraries can be installed easily with **PIP**, the Python package installer. To install the base requirements, open a terminal, and enter:

```
pip install PyQt
pip install Twisted
pip install PyOpenSSL
pip install service_identity
```

If you're using MERK on Windows, also enter:

```
pip install pywin32
```

Once all the requirements are installed, unzip the downloaded archive of MERK, use the terminal to navigate to the directory you unzipped MERK to, and type:

```
python merk.py
```

Updating MERK

As MERK stores all its configuration files separate from the executable/installation, updating MERK to the latest version is easy.

Zip File Version

You can do this one of two ways: either delete **merk.exe** and the **lib** folder, wherever you extracted them do, and unzip the new version of MERK in the same folder; or unzip the new version of MERK in the same directory and overwrite all files.

Installer Version

This version of MERK is even easier to update. Just download the installer of the newer version of MERK, unzip **setup.exe**, and double click on it. You don't have to uninstall the older version, the new version will overwrite the old one.

Command-Line Arguments and Options

The command-line interface of MERK works identically on all platforms.

```
usage: python merk.py [--ssl] [-p PASSWORD] [-c CHANNEL[:KEY]] [-C SERVER:PORT[:PASSWORD]]
                      [-S SERVER:PORT[:PASSWORD]] [-n NICKNAME] [-u USERNAME] [-a NICKNAME]
                      [-r REALNAME] [-h] [-d] [-x] [-t] [-R] [-o] [-f] [-s FILE]
                      [--config-name NAME] [--config-directory DIRECTORY] [--config-local]
                      [--scripts-directory DIRECTORY] [--user-file FILE]
                      [--config-file FILE] [--reset] [--reset-user]
                      [--reset-all] [-Q NAME] [-D] [-L]
                      [SERVER] [PORT]

Connection:
  SERVER                  Server to connect to
  PORT                    Server port to connect to (6667)
  --ssl, --tls            Use SSL/TLS to connect to IRC
  -p, --password PASSWORD           Use server password to connect
  -c, --channel CHANNEL[:KEY]        Join channel on connection
  -C, --connect SERVER:PORT[:PASSWORD]   Connect to server via TCP/IP
  -S, --connectssl SERVER:PORT[:PASSWORD]  Connect to server via SSL/TLS

User Information:
  -n, --nickname NICKNAME          Use this nickname to connect
  -u, --username USERNAME          Use this username to connect
  -a, --alternate NICKNAME         Use this alternate nickname to connect
  -r, --realname REALNAME          Use this realname to connect

Options:
  -h, --help                   Show help and usage information
  -d, --donotsave              Do not save new user settings
  -x, --donotexecute            Do not execute connection script
  -t, --reconnect               Reconnect to servers on disconnection
  -R, --run                     Don't ask for connection information on start
  -o, --on-top                  Application window always on top
  -f, --full-screen             Application window displays full screen
  -s, --script FILE             Use a file as a connection script

Files and Directories:
  --config-name NAME            Name of the configuration file directory (default: .merk)
  --config-directory DIRECTORY  Location to store configuration files
  --config-local                Store configuration files in install directory
  --scripts-directory DIRECTORY Location to look for script files
  --user-file FILE              File to use for user data
  --config-file FILE            File to use for configuration data
  --reset                       Reset configuration file to default values
  --reset-user                  Reset user file to default values
  --reset-all                   Reset all configuration files to default values

Appearance:
  -Q, --qtstyle NAME            Set Qt widget style (default: Windows)
  -D, --dark                     Run in dark mode
  -L, --light                    Run in light mode
```

Using Command-Line Options

MERK's command-line options allow users to do many things on startup. All of these uses are completely optional, and never have to be used. Most command-line options feature a long version (for example **--donotexecute**) and a shorter version (**-x**, which does the same thing).

If user settings are in place (that is, the default nickname, username, etc), command-line options can be used to connect to one or more IRC servers automatically on startup. For example, to automatically connect to the DALnet IRC network, you can use:

```
merk.exe us.dal.net 6687
```

This will automatically connect to DALnet, executing any connection script previously set up with MERK. To prevent the connection script from executing, try:

```
merk.exe --donotexecute us.dal.net 6667
```

Multiple servers can be connected to, as well, though the method is a little different. Use the **-C** option to connect to normal IRC servers, and the **-S** option to connect to IRC servers via SSL/TLS. In the next example, we're going to connect to the Libera network via SSL/TLS, and DALnet:

```
merk.exe -S irc.libera.chat:6697 -C us.dal.net:6667
```

If you want MERK to skip asking for a server to connect to on startup, use the **--run** option:

```
merk.exe --run
```

MERK can even be configured to run on a USB thumb drive! For this example, assume that MERK has been extracted into the root directory of a USB thumb drive. In the same directory as **merk.exe**, create a text file, and type this into it:

```
merk.exe --config-local
```

Save this file as **merk.bat**. Now, to run MERK off of the thumb drive, double click on **merk.bat** (which is a Windows batch file²). This will run MERK normally, but store all of the configuration files in a folder named **.merk** in the drive where you're running MERK from. MERK is now completely portable!

² https://en.wikipedia.org/wiki/Batch_file

Resetting MERK to Default Settings

If your installation of MERK becomes unusable or for any other reason, you can reset MERK back to default settings with the following [command-line option](#):

```
python merk.py --reset
```

If you are running MERK with the PyInstaller executable, use:

```
merk.exe --reset
```

To reset all user settings, use the **--reset-user** command-line option. This will remove all user settings, including your nickname, alternate username, username, realname, connection history, and any connection scripts:

```
python merk.py --reset-user
```

To reset *all* settings, and return MERK configuration files to their default state with all default settings, use **--reset-all**. This will reset both your user file, **user.json**, and the settings file, **settings.json**, to all default values:

```
merk.exe --reset-all
```

Directories and Configuration Files

MERK stores all its settings in a directory it creates in the user's home directory, named `.merk`. Inside this directory, MERK creates:

- **logs**. This directory is where MERK stores channel and private chat logs.
- **styles**. This directory is where MERK stores text style files, and the palette used for dark mode.
- **scripts**. This directory is where MERK stores, and first looks for, scripts. This is the default directory chosen when running a script via the server window toolbar, input menu, or right click menus, or when saving a script in the editor.
- **plugins**. This directory is where MERK looks for and loads any installed plugins from. To install a plugin, simply copy the plugin's Python file into this directory and restart MERK.
- **settings.json**. This file is where MERK stores and loads application settings.
- **user.json**. This file is where MERK stores user information, such as the chosen nickname, username, and the like, as well as the application's connection history and any connection scripts.

When using the [`/script` command](#), if a full filename is not provided, MERK will look for the script in several locations, in order:

1. The **scripts** directory.
2. The settings directory (by default, `.merk` in the user's home directory).
3. The application's installation directory.

First, MERK will attempt to find the script using the provided filename, and if the script is still not found, it will append the default file extension (which is `.merk`) to the filename and search again. This same pattern is used with the `/edit` and `/insert` commands.

These folders can be opened in your default file manager from the client by clicking on the appropriate entry in the "Directories" sub-menu, near the bottom of the "Tools" menu.

New User Help

Most dialogs feature text explaining how the dialog or the settings in it work.

The explanation text from the channel list dialog.

While new users of MERK may find these helpful, experienced users may not want to see them. To hide the help text on dialogs, turn on "Simplified dialogs" in the settings menu or the settings dialog:

The "Simplified dialogs" option in the "Settings" menu. Click this entry to simplified dialogs on and hide the help text.

The "Simplified dialogs" option on the first page of the "Settings" dialog.

"Simplified dialogs" is turned off by default, showing the help text on dialogs every time a dialog is opened.

Connection Dialog

When you first run MERK, a connection dialog is displayed, allowing you to connect to an IRC server. The dialog has three tabs: **User Information**, **Internet Relay Chat Server**, and **Connection Script**.

- **User Information** is where the user enters their various user information for connection. **Nickname** is the nickname you'd like to use, and **Alternate** (optional) will be used if that nickname is already taken; if both are taken, a random number is generated and added to **Nickname**.
- **Internet Relay Chat Server** is where the user enters the IRC server to connect to. By default, the last server MERK connected to is pre-entered. **Host** is the IP address or hostname of the desired IRC server, and **Port** is the server's port. **Password** is the server's password, if one is required; leave blank if one is not required. Click **Connect via SSL/TLS** to connect via SSL/TLS, and click **Reconnect** if MERK should automatically try to reconnect on disconnection. Click **Execute connection script** to execute the connection script on the next tab as soon as MERK connects to the server.
- **Connection Script** has a small script editor for editing the script MERK will execute upon connection to the server. The syntax highlighting settings can be edited with the "Settings" dialog. If **Execute connection script** is unchecked, this script will not be executed.
- **Save to user settings files**, if checked, will save any information entered into the dialog to **user.json**, and will be loaded automatically the next time MERK is started up.

Click **Connect** to connect to the IRC server using the entered information, or **Exit** to close MERK. To start MERK without connecting to a server, click **Open MERK**.

Server Windows

Server windows are the first windows you will see in MERK; they appear as soon as connection to an IRC server begins. Server windows behave differently from channels or private chat windows: closing a server window does not disconnect from the server, it only hides the window. To view a hidden server window, click on its entry in the "Windows" menu or the system tray menu. You cannot chat to other users from a server window without using commands like **/msg** or **/notice**.

1. **Toolbar.** Buttons that perform basic actions; some on the IRC server, such as joining a channel, changing your nickname, and setting your away status, and others on the client, like selecting a script to run, refreshing the channel list from the server, and opening the channel list dialog. Clicking the button labeled "TCP/IP" (for normal connections) or "SSL/TLS" (for encrypted connections) will show a menu with information about the server.
2. **Connection uptime.** This displays how long MERK has been connected to the server.
3. **Disconnect.** Pressing this button issues a **QUIT** command and quickly disconnects from the IRC server.
4. **Display.** Displays any messages from the server, as well as notices, outgoing private messages, and the like.
5. **Text input widget.** Type commands in here, and press "enter" to execute them.
6. **Input menu.** Clicking on this brings up a menu that allows you to do various tasks, like changing the spellchecker's language. This button is present on channel or private message windows, too.

Channel Windows

Closing a channel window leaves the channel.

1. **Mode Editor** and **Banlist**. The mode editor button displays a menu that allows the user to set or remove popular channel modes, if their status allows it; if they are not a privileged enough user, the button is hidden. The banlist displays a list of users that have been banned from the channel; if the banlist is empty, the button is hidden.
2. **Name and mode display**. Here, the channel name and any channel modes are displayed.
3. **Topic**. The channels topic is displayed here. Click on the topic to edit it, and press enter to send any changes to the server.
4. **User count**. How many users are currently in the channel
5. **Chat display**. Channel chat, as well as system messages, are displayed here.
6. **User list**. A list of users in the channel is displayed here. Privileged users have special icons next to their name (green for channel operators, blue for voiced users, etc.), and normal users do not. Nicknames are displayed in bold if the users are present, and in normal weight if they are away. Double click a user's name to open a private chat window.
7. **Nickname**. This displays the currently used nickname, and any user modes set.
8. **Text input widget**. Type your chat or commands here, and press "enter" to send them to the server or client.
9. **Uptime**. This displays how long the client has been connected to the channel.
10. **Input menu**. Clicking on this brings up a menu that allows you to do various tasks, like changing the spellchecker's language.

Private Chat Windows

Closing a private chat window does not leave the chat, or block the sender; it only closes the window.

1. **Chat display.** Private chat is displayed here, as well as system messages.
2. **Nickname.** This displays the currently used nickname, and any user modes set.
3. **Text input widget.** Type your chat or commands here, and press "enter" to send them to the server or the client.
4. **Input menu.** Clicking on this brings up a menu that allows you to do various tasks, like changing the spellchecker's language.

Style Editor

MERK has a text style engine that colors and styles all chat text, and can be edited by users with the style editor.

1. **Style selector.** Select what text style to edit. When launched from the "Tools" menu, this will default to editing the default text style; when launched from context menus or the `/style` command, the text style of the window that launched the style editor will be selected. The text style of any window currently in use can be selected.
2. **Display.** This is what the text style will look like in the client. Any changes in color or style will be displayed here instantly. If editing the default text style, or the text style of a channel, an example user list is shown as how it will appear in the client. The example user list is not shown when editing the text style of server windows or private chats.
3. **Background and foreground color.** Set the color of the text and the background color here.
4. **Message styles.** Change the color and style of individual message types here.
5. **Set colors to app default.** Set all colors to the default style that ships with MERK. This is different from the "default" style that is applied to server windows and any windows that do not have a style.
6. **Load style.** Here, you can open any existing MERK style file for editing. Colors and styles will be loaded and displayed.
7. **Load default.** This will load in whatever style the user has set as the default text style. This button is disabled when editing the default text style.
8. **Save style as....** Save this style to a file. It will not be applied, only saved to a file.
9. **Apply and Cancel.** Applying this style automatically saves it. Pressing the "cancel" button closes the dialog, and all changes are discarded.

How Text Styles Are Applied

All chat windows start by using the default style. All text styles currently in use can be edited with the "Style Editor", found in the "Tools" menu

All chat windows can have their own styles which can be edited by selecting the "Style Editor" option from the "Tools" menu, or "Edit [NAME]'s text style" in the input options menu, or the chat display right click menu. Styles for channel and private chat windows are saved with the IRC network of the channel or private chat in mind, so they will load no matter which server the client is connected to. For example, if the user has set a text style for the #merk channel on the EFnet network, it will load and be applied to the #merk channel window if the user is connected to **irc.underworld.no** on port 6667, **irc.choopa.net** on port 9999, or **irc.prison.net** on port 6667, as all of these servers are on the EFnet IRC network.

Server window text styles are specific to the server being connected to, regardless of what network the server is on. So, if the user has set a style for **irc.prison.net** on port 6667, the server window text style for that connection will be loaded. If the user connects to **irc.choopa.net** on port 9999, the default style will be loaded; even though both servers on the EFnet network, they are still different servers.

Script Editor

To launch the script editor, use the **/edit** command, or select **Script Editor** from the "Tools" menu

1. **File and Edit Menus.** All the normal selections of a text editor, like opening and saving files, cut and paste, find and replace, etc. Connection scripts can also be opened for editing, as well as created.
2. **Commands.** Each entry in this menu allows the user to insert a command into the open script. Click the desired command, fill out the entries in the dialog that pops up, if needed, and the command will be inserted into the script.
3. **Aliases.** Insert built-in aliases into the script.
4. **Run.** Run the currently open script in any context/window available. The user also can run the script in all contexts/windows simultaneously. Scripts are executed with no arguments and no filename.
5. **Script display.** Features syntax highlighting. Colors used for the display can be set in the "Settings" dialog.
6. **Filename.** The currently open script's filename is displayed here.
7. **Line number.** The line number the cursor is currently on.

The colors and styles used for the syntax highlighting can be changed in the "Settings" dialog. Comments, commands, channels, aliases, and script-only commands can be styled individually. These colors and styles will also be used in the "Connection Script" tab of the [connection dialog](#).

Log Manager

The log manager allows users to view, delete, and export MERK logs. It can be launched from the "Tools" menu

1. **Logs.** A full list of all logs in MERK. Hover the mouse over the log name to see what IRC network the log is from. Click a log name to view information about the log, as well as use export options. Double click a log name to view the contents of a log.
2. **Search.** Search the log for specific words. Typing in the terms and pressing enter will find the first instance of the term in the log; hitting enter again will find the next, and so on.
3. **Next Result and Previous Result.** Move forward and backwards in the word search results.
4. **Log Viewer and Export Tabs.** Click tabs to switch functions. The **Export** tab has settings and functionality to export MERK logs to JSON or a custom delimited format.
5. **Log display.** Logs are loaded in full for viewing. For longer logs, this may take some time. Logs use the whatever default text style the user has set.
6. **Log information.** Contains the log name, what IRC network the log is from, how many lines of chat the log contains, and how long it took to render the entire log, if the log is being viewed.
7. **Log filename.** The full filename of the current log.

Additional log options can be seen by right-clicking on the log's name:

If the "Open native JSON log" option is selected, the JSON file that MERK uses will be opened in the default application that the user's operating system to open JSON files. There is additional information in the native log format that tells MERK how to render the log for viewing; to use MERK logs with other applications, the log should be exported to strip this information out.

Logs that are very large will not be fully loaded for the log display; only the last 5000 lines of chat are loaded, as it can take up to a minute to render a log this large, depending on the speed of the computer running MERK. This can be changed by using the [/config](#) command: the setting `log_manager_maximum_load_size` sets the maximum number of lines to load.

Hotkeys

The hotkey manager allows users to add or delete hotkeys that execute commands on whatever active subwindow has focus.

The hotkey manager, showing a few bound hotkeys. Hotkeys can be added by clicking the + button, or removed by selecting a hotkey in the list and clicking the – button. Save all hotkeys to the configuration file by clicking the disk button.

Commands executed by hotkeys are treated *exactly* as if the command was typed into a subwindow's text input widget and the return key was pressed.

Ignores

The ignore manager allows users to add, edit, and remove entries in the ignore list, preventing chat from users with specific nicknames or hostmasks from appearing in chat, or preventing them from sending the user private messages, notices, and the like.

The ignore manager. Add nicknames or hostmasks to the ignore list by clicking the + button, and select an entry and click the - button to remove an entry. Double click on an entry to edit that entry. All chat windows will be automatically updated with the new ignore list immediately upon adding or removing an entry if "Automatically update chats" is checked. Click on the refresh button to update chat windows manually.

If a user is ignored, their chat will not appear in any chat window, and any private chat or notices will not open any chat windows. Any "ignored" chat is still received by MERK, and added to any chat logs, and will appear in chat windows if the ignore entry is removed.

Updating chat windows may take some time; chat must be reloaded to hide or show any ignored or unignored entries. If "Automatically update chats" is checked, this update will be done *every time* an entry is added, edited, or removed.

Plugins

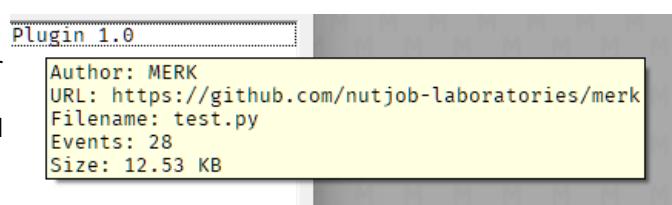

The plugin manager allows users to create, edit, delete, and load MERK plugins. A version of the script editor, modified for Python programming, is used to create and edit MERK plugins in-app.

The plugin manager. Any plugins loaded into MERK are displayed in the list. Click the + button to create a new plugin, opening up a "blank" plugin in the editor. Select a plugin and click the – button to delete a plugin. Click on the **folder** to import a plugin; select a MERK plugin in the "import file" dialog that comes up, and it will be moved into the **plugins** directory and the plugin list will be reloaded. Click on the refresh button to reload any plugins (new and old) in the **plugins** directory. Double-click on a plugin entry to edit that plugin in the Python editor.

For more information on how plugins work, and what they can do, please see [**Plugins and Plugin Development**](#). MERK doesn't come with any plugins, so unless you've installed or created any plugins, this list will be empty when you first install MERK.

Hover the mouse above an entry in the plugin manager to see information about that plugin. The author, URL, filename, how many events the plugin responds to, and the size of the plugin in memory is displayed.

To install a plugin, simply copy the Python file for the plugin into the **plugins** directory, located in the same [directory where MERK stores configuration files, logs, scripts, and styles](#). Press the "refresh" button in the plugin manager, or restart MERK to load the plugin into

memory. The other option is to press the "Import Plugin" button in the manager, which allows the user to select a file to move into the plugins directory before automatically loading it. Clicking the "Create new plugin" button in the manager will open up the plugin editor, a special version of the [script editor](#) for Python code, and load in a skeleton³ plugin for the user to edit. The skeleton plugin has all plugin events pre-defined, and more information about writing plugins is in the comments of the skeleton.

The screenshot shows a window titled "Untitled" containing Python code. The code defines two functions: `lost` and `message`. The `lost` function takes arguments `self` and `**args`, and extracts `client` from `args`. It contains a multi-line comment explaining that it is triggered whenever a channel or private message is received, and the channel will be the client's nickname. The `message` function also takes `self` and `**args`, and extracts `client`, `channel`, `user`, and `message` from `args`. It contains a multi-line comment explaining its purpose. The code uses standard Python syntax with indentation and docstrings.

```
def lost(self,**args):
    client = args[ "client" ]

    # |-----|
    # | message |
    # |-----|
    #

    # This event is triggered whenever MERC received a channel
    # or private chat message. If the message is a private chat
    # message, the channel will be MERC's nickname.
    #
    # Arguments:
    #   client = The Twisted IRC object that triggered the event
    #   channel = The channel the message was sent to
    #   user = The user that sent the message
    #   message = The message
    #

def message(self,**args):
    client = args[ "client" ]
    channel = args[ "channel" ]
    user = args[ "user" ]
    message = args[ "message" ]

    # |-----|
    # | mode |
    # |-----|
    #
```

A plugin skeleton, open in the Python version of the script editor.

The Python script editor features syntax highlighting and auto-indent. The only way to open the Python script editor is with the plugin manager, either by creating a plugin or by double-clicking on a plugin to edit it. Python script editor windows appear normally in the [windowbar](#) and the "Windows" menu, with the only difference being that the window's icon is the "plugin" icon rather than the normal "script" icon.

³ A program skeleton may also be utilized as a template that reflects syntax and structures... [Wikipedia](#)

The Windowbar

The "windowbar" is a widget that is located by default on the top of the main window that displays a list of open subwindows. Clicking on a window's name switches "focus" to that window, bringing it to the front; double click the window name to bring the window to the front and maximize it. By default, the windowbar only shows channel windows, private chat windows, and script editor windows, but you can use the "Settings" dialog (or the windowbar's right click menu) to show other window types. Think of the windowbar as a sort of task manager, only for windows in MERK.

Right click on an entry in the windowbar for more options. Each window type shows different options. Right click on the windowbar itself to change settings for the windowbar. Most things about the windowbar can be changed, including the order windows are shown, what windows are shown, whether icons are shown on entries, and more.

The windowbar right click menu for a server window.

Although immobile by default, the right click menu and the "Settings" dialog can make the windowbar movable; the windowbar can float, or be "docked" at the bottom or the top of MERK's main window.

Regular and Dark Mode

MERK can be operated in "normal" mode, seen above to the left, or in "dark" mode, on the right. To switch to "dark" mode, select it in the "Settings" menu or in the "Settings" dialog. MERK will have to be restarted for it to take effect, and you'll be prompted to restart MERK automatically.

For more advanced users, if you want to edit the palette that "dark" mode uses, all of the colors used by the application are stored in a file in the **styles** directory named **dark.palette**. The file format is specific to MERK, but you can edit it with a text editor. All colors are stored in the hexadecimal format used by HTML. To re-create the file and reset the "dark" mode values back to the default, delete **dark.palette** and restart MERK; the application will regenerate the file with default values.

Commands and Scripting Guide

Command List

IRC Commands

All of these commands are related to IRC, in some way, shape, or form. Most of them are present in most other modern IRC clients.

Command	Description
/away [MESSAGE]	Sets status as "away"
/back	Sets status as "back"
/ctcp REQUEST USER	Sends a CTCP request to a user. Valid requests are TIME, VERSION, USERINFO, SOURCE, or FINGER
/invite NICKNAME CHANNEL	Sends a channel invitation
/finger TEXT...	Sets the CTCP FINGER response. Pass * as the argument to clear the FINGER response text.
/join CHANNEL [KEY]	Joins a channel
/kick CHANNEL NICKNAME [MESSAGE]	Kicks a user from a channel
/knock CHANNEL [MESSAGE]	Requests an invitation to a channel
/list [TERMS]	Lists or searches channels on the server; use "*" for multi-character wildcard and "?" for single character
/me MESSAGE...	Sends a CTCP action message to the current chat
/mode TARGET MODE...	Sets a mode on a channel or user
/msg TARGET MESSAGE...	Sends a message
/nick NEW_NICKNAME	Changes your nickname
/notice TARGET MESSAGE...	Sends a notice
/oper USERNAME PASSWORD	Logs into an operator account
/part CHANNEL [MESSAGE]	Leaves a channel
/ping USER [TEXT]	Sends a CTCP ping to a user
/quit [MESSAGE]	Disconnects from the current IRC server
/quitall [MESSAGE]	Disconnects from all IRC servers
/raw TEXT...	Sends unprocessed data to the server
/reclaim NICKNAME	Repeatedly attempts to change nickname to NICKNAME until successful; by default, attempts are made every 30 seconds
/refresh	Requests a new list of channels from the server
/time	Requests server time
/topic CHANNEL NEW_TOPIC	Sets a channel topic
/userinfo TEXT...	Sets the CTCP USERINFO response. Pass * as the argument to clear the USERINFO response text.
/version [SERVER]	Requests server version

Command	Description
/who NICKNAME [o]	Requests user information from the server
/whois NICKNAME [SERVER]	Requests user information from the server
/whowas NICKNAME [COUNT] [SERVER]	Requests information about previously connected users

All Other Commands

These commands are specific to MERK, and are for using and manipulating the client. Commands with a gray background are for use in scripts *only*; they cannot be used in the text input widget, and will only produce an error. [Some of these commands cannot be used in scripts.](#)

Command	Description
/alias [TOKEN] [TEXT...]	Creates an alias that can be referenced by \$TOKEN . Call with only TOKEN as the argument to see TOKEN 's value. If TEXT is a mathematical statement, it will be evaluated, with the resulting value stored as the alias' value. Call without any arguments to see all aliases and their values.
/bind SEQUENCE COMMAND...	Executes COMMAND every time key SEQUENCE is pressed. SEQUENCE should contain no spaces, and should be a string like "Ctrl+M" or "Alt+Space". COMMAND will be executed in whatever window/context has focus when SEQUENCE is pressed. To save binds to the configuration file, pass save as the only argument.
/clear [SERVER] [WINDOW]	Clears a window's chat display. SERVER is optional if WINDOW belongs to the same context.
/close [SERVER] [WINDOW]	Closes a subwindow. SERVER is optional if WINDOW belongs to the same context.
/config [SETTING] [VALUE...]	Changes a setting, or searches and displays one or all settings in the configuration file
/config export [FILENAME]	Exports the current configuration file
/config import [FILENAME]	Imports a configuration file into settings
/connect SERVER [PORT] [PASSWORD]	Connects to an IRC server
/connectssl SERVER [PORT] [PASSWORD]	Connects to an IRC server via SSL
context WINDOW_NAME	Moves execution of the script to WINDOW_NAME ; can only be called from scripts
/delay SECONDS COMMAND...	Executes COMMAND after SECONDS seconds
/edit [FILENAME]	Opens a script in the editor; if called without an argument, opens an editor window
end	Immediately ends a script. Can only be called from scripts.
exclude WINDOW...	Prevents a script from executing in WINDOW 's context. Multiple WINDOWS can be specified. Can only be called from scripts.
/exit [SECONDS]	Exits the client, with an optional pause of SECONDS before exit
/find [TERMS]	Finds filenames that can be found by other commands, like /script or /edit . If called without any arguments, /find will list all files visible to commands. Can use * for multi-character wildcards and ? for single character wildcards.

/focus [SERVER] [WINDOW]	Sets focus on a subwindow. SERVER is optional if WINDOW belongs to the same context.
/fullscreen	Toggles full screen mode
goto LINE_NUMBER	Moves execution of the script to LINE_NUMBER . The only script-only command that can be issued from an if command. Can only be called from scripts.
halt [MESSAGE...]	Halts a script's execution, and displays an error MESSAGE with line number and file name. Can only be called from scripts.
/help [COMMAND]	Displays command usage information
/hide [SERVER] [WINDOW]	Hides a subwindow. SERVER is optional if WINDOW belongs to the same context.
if VALUE1 OPERATOR VALUE2 COMMAND...	Executes COMMAND if VALUE1 and VALUE2 are true, depending on OPERATOR . Valid OPERATORS are (is) (result is true if VALUE1 and VALUE2 are equal), (not) (result is true if VALUE1 and VALUE2 are not equal), (in) (result is true if VALUE1 is contained in VALUE2), (gt) (result is true if VALUE1 is a greater number than VALUE2), (lt) (result is true if VALUE1 is a lesser number than VALUE2), (ne) (result is true if VALUE1 and VALUE2 are numbers and are not equal), and (eq) (result is true if VALUE1 and VALUE2 are numbers and are equal). Can only be called from scripts.
/ignore USER	Hides a USER 's chat in all chat windows. This can be set to a nickname or hostmask. Capitalization is ignored. Use * as multiple character wildcards, and ? as single character wildcards.
insert FILE [FILE...]	Inserts the contents of FILE where it appears in the script. FILE should be a MERK script. If a filename contains spaces, put it in quotation marks. Multiple files can be passed as arguments. Can only be called from scripts.
/macro NAME SCRIPT [USAGE] [HELP]	Creates a macro, executable with /NAME , that executes SCRIPT . USAGE and HELP are used for the command list displayed with /help .
/maximize [SERVER] [WINDOW]	Maximizes a subwindow. SERVER is optional if WINDOW belongs to the same context.
/minimize [SERVER] [WINDOW]	Minimizes a subwindow. SERVER is optional if WINDOW belongs to the same context.
/move [SERVER] [WINDOW] X Y	Moves a subwindow to X (left and right) and Y (up and down) coordinates. SERVER is optional if WINDOW belongs to the same context.
/msgbox MESSAGE...	Displays a messagebox with a short message
only WINDOW...	Restricts a script to only executing in WINDOW 's context. Multiple WINDOWS can be specified. Can only be called from scripts.

/play FILENAME	Plays a WAV file
/print [WINDOW] TEXT...	Prints text to a window
/prints [WINDOW] TEXT...	Prints a system message to a window
/private NICKNAME [MESSAGE]	Opens a private chat subwindow for NICKNAME
/random ALIAS LOW HIGH	Generates a random number between LOW and HIGH and stores it in ALIAS
/reconnect SERVER [PORT] [PASSWORD]	Connects to an IRC server, reconnecting on disconnection
/reconnectssl SERVER [PORT] [PASSWORD]	Connects to an IRC server via SSL, reconnecting on disconnection
/rem [TEXT...]	Does nothing. Can be used as a target for goto
/resize [SERVER] [WINDOW] WIDTH HEIGHT	Resizes a subwindow. SERVER is optional if WINDOW belongs to the same context.
restrict channel server private	Prevents a script from running if it is not being executed in a channel , server , or private chat window. Up to two window types can be set. Can only be called from scripts.
/restore [SERVER] [WINDOW]	Restores a subwindow. SERVER is optional if WINDOW belongs to the same context.
/s FILENAME [ARGUMENTS]	A shortcut for the /script command.
/script FILENAME [ARGUMENTS]	Executes a list of commands in a file. If the script has a file extension of .merk , it may be omitted from FILENAME .
/shell ALIAS COMMAND...	Executes an external program, and stores the output in an alias
/show [SERVER] [WINDOW]	Shows a subwindow, if hidden; otherwise, shifts focus to that subwindow. SERVER is optional if WINDOW belongs to the same context.
/style [SERVER] [WINDOW]	Opens a window's text style editor.
/unalias TOKEN	Deletes the alias referenced by \$TOKEN
/unbind SEQUENCE	Removes a bind for key SEQUENCE . To remove all binds, pass * as the argument
/unignore USER	Un-hides a USER 's chat in all chat windows. This can be set to a nickname or hostmask. Capitalization is ignored. To un-hide all users, use * as the argument.
usage NUMBER [MESSAGE...]	Prevents a script from running unless NUMBER or more arguments are passed to it, and displays MESSAGE . Can only be called from scripts
/user [SETTING] [VALUE...]	Changes a user setting, or searches and displays one or all settings in the user file. Pass * as VALUE to set a setting as blank
wait SECONDS	Pauses script execution for SECONDS ; can only be called from scripts

/window [COMMAND] [X] [Y]	Manipulates the main application window. Valid commands are move , resize , maximize , minimize , restore , readme , settings , logs , hotkey , ignore , plugin , restart , cascade , tile , next , previous . Call with no arguments to see window information and a list of subwindows.
/xconnect SERVER [PORT] [PASSWORD]	Connects to an IRC server & executes connection script
/xconnectssl SERVER [PORT] [PASSWORD]	Connects to an IRC server via SSL & executes connection script
/xreconnect SERVER [PORT] [PASSWORD]	Connects to an IRC server & executes connection script, reconnecting on disconnection
/xreconnectssl SERVER [PORT] [PASSWORD]	Connects to an IRC server via SSL & executes connection script, reconnecting on disconnection

Script-Only Commands

These commands can only be called from scripts. Attempts to use them in the text input widget will fail and show an error.

Command	Description
context WINDOW_NAME	Moves execution of the script to WINDOW_NAME ; can only be called from scripts
end	Immediately ends a script. Can only be called from scripts.
exclude WINDOW...	Prevents a script from executing in WINDOW 's context. Multiple WINDOWS s can be specified. Can only be called from scripts.
if VALUE1 OPERATOR VALUE2 COMMAND...	Executes COMMAND if VALUE1 and VALUE2 are true, depending on OPERATOR . Valid OPERATORS are (is) (result is true if VALUE1 and VALUE2 are equal), (not) (result is true if VALUE1 and VALUE2 are not equal), (in) (result is true if VALUE1 is contained in VALUE2), (gt) (result is true if VALUE1 is a greater number than VALUE2), (lt) (result is true if VALUE1 is a lesser number than VALUE2), (ne) (result is true if VALUE1 and VALUE2 are numbers and are not equal), and (eq) (result is true if VALUE1 and VALUE2 are numbers and are equal). Can only be called from scripts.
goto LINE_NUMBER	Moves execution of the script to LINE_NUMBER . The only script-only command that can be issued from an if command. Can only be called from scripts.
halt [MESSAGE...]	Halts a script's execution, and displays an error MESSAGE with line number and file name. Can only be called from scripts.
insert FILE [FILE...]	Inserts the contents of FILE into the script. FILE should be a MERK script. If a filename contains spaces, put it in quotation marks. Multiple files can be passed as arguments. Can only be called from scripts.
only WINDOW...	Restricts a script to only executing in WINDOW 's context. Multiple WINDOWS s can be specified. Can only be called from scripts.
restrict channel server private	Prevents a script from running if it is not being executed in a channel , server , or private chat window. Up to two window types can be set. Can only be called from scripts.
usage NUMBER [MESSAGE...]	Prevents a script from running unless NUMBER or more arguments are passed to it, displaying MESSAGE . Can only be called from scripts.
wait SECONDS	Pauses script execution for SECONDS ; can only be called from scripts

Context-less Commands

These commands can be called without specifying the channel, chat, or window they are for. They will run in the current context. Commands with a gray background are IRC specific commands.

Command	Description
/bind SEQUENCE COMMAND ...	Executes COMMAND every time key SEQUENCE is pressed. SEQUENCE should contain no spaces, and should be a string like "Ctrl+M" or "Alt+Space". COMMAND will be executed in whatever window/context has focus when SEQUENCE is pressed. To save binds to the configuration file, pass save as the only argument.
/clear	Clears the current window's chat display
/close	Closes the current subwindow
/focus	Sets focus on the current subwindow
/hide	Hides the current subwindow
/invite NICKNAME	Sends a channel invitation to the current channel
/kick NICKNAME [MESSAGE]	Kicks a user from the channel
/maximize	Maximizes the current subwindow
/me MESSAGE ...	Sends a CTCP action message to the current chat
/minimize	Minimizes the current subwindow
/mode MODE ...	Sets a mode on the current channel
/move X Y	Moves the current subwindow to X (left and right) and Y (up and down) coordinates.
/part [MESSAGE]	Leaves the channel
/print TEXT ...	Prints text to the current window
/prints TEXT ...	Prints a system message to the current window
/resize WIDTH HEIGHT	Resizes the current subwindow
/restore	Restores the current subwindow
/show	Shows the current subwindow, if hidden
/style [SERVER] [WINDOW]	Opens a window's text style editor.
/topic NEW_TOPIC	Sets the current channel's topic
/unbind SEQUENCE	Removes a bind for key SEQUENCE . To remove all binds, pass * as the argument

Subwindow and Window Management Commands

These commands are used to manipulate both the main application window, and the subwindows it contains. For all of these commands except for `/window`, if the **SERVER** and **WINDOW** arguments are left out, the command will be enacted on the subwindow the command was entered in.

Command	Description
<code>/close [SERVER] [WINDOW]</code>	Closes a subwindow
<code>/focus [SERVER] [WINDOW]</code>	Sets focus on a subwindow
<code>/hide [SERVER] [WINDOW]</code>	Hides a subwindow
<code>/maximize [SERVER] [WINDOW]</code>	Maximizes a window
<code>/minimize [SERVER] [WINDOW]</code>	Minimizes a window
<code>/move [SERVER] [WINDOW] X Y</code>	Moves a subwindow to X (left and right) and Y (up and down) coordinates.
<code>/resize [SERVER] [WINDOW] WIDTH HEIGHT</code>	Resizes a subwindow
<code>/restore [SERVER] [WINDOW]</code>	Restores a window
<code>/show [SERVER] [WINDOW]</code>	Shows a subwindow, if hidden
<code>/window [COMMAND] [X] [Y]</code>	Manipulates the main application window. Valid commands are <code>move</code> , <code>resize</code> , <code>maximize</code> , <code>minimize</code> , <code>restore</code> , <code>readme</code> , <code>settings</code> , <code>logs</code> , <code>hotkey</code> , <code>ignore</code> , <code>plugin</code> , <code>restart</code> , <code>cascade</code> , <code>tile</code> , <code>next</code> , <code>previous</code> . Call with no arguments to see window information and a list of subwindows.

Additional Command Help

- **wait** – *Can only be called from scripts*
- **context** – *Can only be called from scripts*
- **end** – *Can only be called from scripts*
- **usage** – *Can only be called from scripts*
- **restrict** – *Can only be called from scripts*
- **insert** – *Can only be called from scripts*
- **only** – *Can only be called from scripts*
- **exclude** – *Can only be called from scripts*
- **if** – *Can only be called from scripts*
- **goto** – *Can only be called from scripts*
- **halt** – *Can only be called from scripts*

Most commands can be issued in both the text input widget and scripts. There are eleven commands, however, that can *only* be issued in scripts: **wait**, **context**, **usage**, **restrict**, **insert**, **only**, **exclude**, **if**, **goto**, **halt**, and **end**. These eleven commands *cannot* be used in the text input widget.

Most commands require a context to be executed in (see [Context](#)). Commands that can be [issued without explicitly specifying a context](#) are **/clear**, **/invite**, **/kick**, **/me**, **/mode**, **/part**, **/topic**, **/maximize**, **/minimize**, **/hide**, **/show**, **/close**, **/print**, **/prints**, **/resize**, **/move**, **/focus**, and **/restore**; they will be executed in whatever the current context is, and may not function correctly if the current context does not support that command (for example, calling **/invite** from a server window). The only exception is **/me**: if called from the text input widget of a channel or private chat window, it will send a CTCP action to the current window, using *all* arguments as the text to send in the message. If **/me** is called from a server window, the first argument specifies the channel or private chat to send the CTCP message to. For example, to send a CTCP message containing "is using MERK" to the **#merk** channel, you could call **/me #merk is using MERK** from a server window. When calling **/me** from a script, *the command will always send to the current chat if running in a channel or private chat window, and must specify the context if running in a server window*. If a context is specified as the first argument to **/me**, and the command is executed in a channel or private chat window, the specified context will be sent as part of the CTCP action message.

The [goto command](#) cannot be used to "jump" to a line that contains any script-only command other than **end**. If the "jumped to" line contains *any* script-only command besides **end**, the script will display an error and end execution. Use the [/rem command](#) for a target line that "does nothing".

Most commands that require a numerical argument require an integer; that is, a whole or natural number⁴. Several commands can take floating-point numbers⁵ as arguments, allowing for fractional numbers: **if**, **wait**, **/delay**, and **/exit**. As most of these commands' numerical arguments relate to the amount of time to "pause" a command or script's execution,

⁴ ...Natural numbers are the numbers 0, 1, 2, 3, and so on. [Wikipedia](#)

⁵ [Wikipedia article on floating-point arithmetic](#)

floating-point numbers allow these commands to "pause" for time periods of less than a second. For example, to "pause" a script for 500 milliseconds, or one half of a second:

```
wait 0.5
```

To convert milliseconds into seconds, divide the number of milliseconds by 1000 to determine the number of seconds. 1 millisecond is 0.001 seconds, 2ms is 0.002 seconds, and so on.

goto

The **goto** command is extremely powerful, and allows a script to "jump" from one line to another line; that is, it can change the sequence of execution of a script. It is not recommended to use **goto** in scripts that contain comments, as comments are stripped out of a script before execution, and may change the line count of a script. Using the **insert** command can also alter the line count of a script, so **goto** should not be used in scripts that use **insert**. Instead, if your script has **insert** or comments, execute scripts with **goto** using the **/script** command.

goto cannot be used to "jump" to a line that contains a script-only command other than **end**. If **goto** is used in this way, an error will be raised, and script execution will halt. The [/rem command](#) can be used as a target, as the command is not a script-only command, and does nothing.

Using **goto** is easy: pass the line number you wish to "jump" to as the only argument. Execution of the script will immediately move to the desired line. For example:

```
1 /print This is the beginning of the script!
2 goto 4
3 /print This line will never be executed.
4 /print This line will ALWAYS be executed!
5 end
```

This script:

1. Prints "This is the beginning of the script!" to the current window
2. "Jumps" immediately to line 4
3. Prints "This line will ALWAYS be executed!" to the current window, which is the result of the command on line 4.
4. End the script.

With the **goto** command in place, line 3 will never be executed, as the **goto** command skips right over it.

goto is the only script-only command that can be called from an **if** command; all other script-only commands are forbidden, and will display an error.

WARNING! There are no protections in place preventing a script from entering an infinite loop⁶. **goto** can lock up or crash MERK.

Please use **goto** carefully and sparingly.

⁶ ...An infinite loop (or endless loop) is a sequence of instructions that, as written, will continue endlessly, unless an external intervention occurs, such as turning off power via a switch or pulling a plug. [Wikipedia](#)

if

The **if** command allows MERK scripts to have a small amount of flow control⁷. It compares two values, and if the values' comparison is true, executes a command. The entity that sets how the comparison works is called the **operator**. MERK has seven operators:

Operator	Description
(is)	True if the first value is equal to the second value. Values are treated as strings, and are case in-sensitive.
(not)	True if the first value is <i>not</i> equal to the second value. Values are treated as strings, and are case in-sensitive.
(in)	True if the first value is contained in the second value; for example, o (in) pop evaluates to true because "pop" has "o" in it. Values are treated as strings, and are case in-sensitive.
(lt)	True if the both values are numbers, and the first value is less than the second value. If either value is not a number, an error is displayed and script execution stops.
(gt)	True if both values are numbers, and the first value is greater than the second value. If either value is not a number, an error is displayed and script execution stops.
(eq)	True if both values are numbers, and the first value is equal to the second value. If either value is not a number, an error is displayed and script execution stops.
(ne)	True if both values are numbers, and the first value is not equal to the second value. If either value is not a number, an error is displayed and script execution stops.

The first value is passed as the first argument, followed by the **OPERATOR**, followed by the second value. All other arguments should contain the command to execute if the comparison is true. **if** can execute almost any command available, with one major exception: **if cannot execute any script-only command other than goto**. Any attempt to use **if** to execute a script-only command besides **goto** will result in a "Line contains no command" error, and script execution will be halted. Remember, **goto** cannot be used to "jump" to a line with any script-only command other than **end**.

As an example, here's a script that tests if the user has a specific nickname (**merk**), and uses the **/reclaim** command if someone use is using the nickname.

```
1 if merk (is) $_NICKNAME goto 4
2 /print "merk" nickname in use, trying to reclaim it...
3 /reclaim merk
4 end
```

This script:

1. Tests if the user's current nickname is **merk**, and if it is, calls **goto** to move execution to line 4, which ends the script
2. Prints a message to the user telling them that the script is going to use the **/reclaim** command
3. Issues the **/reclaim** command to reclaim the **merk** nickname
4. Ends the script

⁷ ...Control flow (or flow of control) describes how execution progresses from one command to the next.
[Wikipedia](#)

Values are tokenized like [script arguments](#); values can have whitespace in them as long as they are contained in quotes. Values can also be mathematical statements, which are evaluated before comparing with the **if** statement's operator. For example, let's assume that you have a number stored in an alias named **mynum**, and you want to determine if that number is even or odd:

```
1 if "$mynum % 2" (eq) 0 goto 4
2 /print $mynum is odd
3 end
4 /print $mynum is even
5 end
```

/rem

The **/rem** command does nothing. It can be used to add "comments" to a script, or as a target for the **goto** command. Since the **goto** command cannot be used to "jump" to a line that contains a script-only command, place a **/rem** command in the line before the desired script-only command, and "jump" to the line with the **/rem** command.

For example, the following code will display an error on line 3 and exit:

```
1 goto 3
2 /print This will never display
3 goto 4
4 /print This will display
```

As line 3, the target the **goto** command "jumps" to in line 1, contains a script-only command (another **goto**), an error will be displayed and the script will exit. To make this script work in exactly the same way (other than updating the target of the second **goto** command), we can use the **/rem** command:

```
1 goto 3
2 /print This will never display
3 /rem This line does nothing
4 goto 5
5 /print This will display
```

/print and /prints

The **/print** command can be used to print text to the current or another window; use the name of the window context as the first argument to print to another window. If this window cannot be found, the text will print to whatever the current window context is. The window specified by the first command must be "connected" to the current context (that is, they share an IRC server connection).

The **/prints** command works exactly the same way, only it prints a "system" message, like the messages emitted by most commands.

Both **/print** and **/prints** can print HTML, and are not written to the log.

```
/* This will print to the current window */
/print Hello world!

/* This will print to the #merk channel window.
   If the client is not in #merk, it will print to the current window. */
/print #merk Hello world!

/* This will print some HTML as a system message */
/prints <i>This is in italics!<i><br><u>And this is underlined on a new line!</u>
```

restrict, only, and exclude

The **restrict** script-only command restricts a script's execution to a specific context. The first argument sets what type of context the script will function in: **server** restricts the script's context to server windows or connection scripts, **channel** restricts the script's context to channel windows, and **private** restricts the script's context to private chat windows. A restricted script will *not* execute in another context, and will show an error. Up to two context types can be passed, so **restrict private channel** would prevent a script from being executed in server windows. So, to restrict a script's execution to chat windows only, you could use:

```
restrict private channel  
/print This will only print to chat windows
```

The similar **only** script-only command can be used to restrict a script's execution to specific contexts; for example, specific channels, server windows, or private chats. Pass the name of the window as an argument to the command; an unlimited number of arguments can be passed to the command. For example, to restrict a script's execution to channels named **#merk** or **#merkirc**, you could use:

```
only #merk #merkirc  
/print This will only print to windows named #merk or #merkirc
```

The **exclude** script-only command works just like the **only** command, only it prevents a script from executing in specific contexts. Pass the name of the window as an argument to the command; an unlimited number of arguments can be passed to the command. To prevent a script's execution in any channel named **#merk** or **#merkirc**, you could use:

```
exclude #merk #merkirc  
/print This will not print to windows named #merk or #merkirc
```

insert

The **insert** script-only command reads in the contents of any file passed as an argument to it, and "inserts" it into the script where it is called. Any built-in aliases (see [Built-In Aliases](#)) in the inserted script will reference the script being executed, not the script being **inserted**, including any arguments passed to the calling script. For example, assume you have a script named **stuff.merk**, and it contains:

```
/print Hello from $_SCRIPT!
```

In another script, we use the **insert** command to insert this file into the script **test.merk**:

```
/print This is my main script!
insert stuff.merk
/print And now my script is complete!
```

Once processed, the script that will be executed will look like:

```
/print This is my main script!
/print Hello from test.merk!
/print And now my script is complete!
```

The **insert** command can be used to insert multiple files into a script; pass each file's name as a separate argument to **insert**, or issue **insert** multiple times. Arguments passed to the **insert** command are tokenized like [script arguments](#), so filenames with spaces in them can be passed to **insert**, as long as they are contained in quotation marks.

inserted files may contain **insert** as well, up to a maximum "depth" of 10 files. That is, a file can **insert** a file that calls **insert**, which can **insert** call a file that calls **insert**, which can **insert** a file that calls **insert**, which can **insert** a file that calls **insert**, and so on, up to a maximum of 10 "layers" of files that call **insert**. Changing this behavior is only possible by [using the /config command](#) on the **maximum_insert_file_depth** setting, or by editing **settings.json** directly with a text editor.

Using the **insert** command can alter the line count of a script, and thus the **goto** command should not be used in an **inserted** script, or in a script that uses **insert**.

/show, /hide, /close, and context

/show and context command switch contexts programmatically, but in slightly different ways. /show will show a window hidden with the /hide command, and also move focus to that window; that means that any commands issued without context will now be issued in that window's context. /hide simply "hides" a window without closing that window. A hidden window is no longer visible, but will still appear in the [windowbar](#); it is *not* closed, and if the window's context is a channel, the client will still be present in that channel. /show will *not* move "focus" to a subwindow, and *cannot* be used to switch context; to switch to a windows context, use the /focus command. /show and /hide can be issued from the text input widget. context can only be issued in scripts, and *completely* moves the script's context to the new window.

Both /hide and /show can take up to two arguments. Pass the **name of the window** to hide or show as the **first argument** if the window shares a context (that is, the same server connection) as the window issuing the command. If the window to be shown or hidden is in another context (a different server connection), pass the **name of the server window** as the **first argument**, followed by the **name of the window** to be shown or hidden as the **second argument**. The IRC server's hostname is normally used for the **name of the server window**, but you can use the address used to connect to the server, or **address:port** to switch to the server window's context. To "select" the server window with one of these commands, use * as the name of the window along with the name of the server.

For the following example, assume that we have two active connections: we are in the channels #merk and #python on **silver.libera.chat**, and the channels #qt and #merk on **lawnmower.undernet.org**. Our test script is executed in #python's context, on **silver.libera.chat**:

```
/* Here, we hide #merk's window in the current context */
/hide #merk

/* Now, we switch context to lawnmower.undernet.org's window */
context lawnmower.undernet.org

/* This shows to #merk, only it's on the UnderNet server,
   not the Libera server */
/show #merk

/* In order to show #merk's window on Libera, we use the server
   argument of /show */
/show silver.libera.chat #merk
```

/close works exactly the same as /show and /hide, only instead of showing or hiding a window, it closes a window. If the window is for a channel, the channel will be left.

You can use the [/window command](#) to see a list of currently available subwindows.

/resize, /move, and /window

The **/resize** and **/move** commands can be used to resize and move MERK subwindows, respectively.

Much like **/hide** and **/show**, **/resize**'s and **/move**'s first two arguments set what window the command is going to work on. Pass the name of the window as the first argument if the window shares the same context as the window the command is being executed in. If the window belongs to the context of another server, pass the name of the server followed by the window name as the first two arguments.

/resize takes two additional arguments: the new width of the subwindow, and the new height of the subwindow. So, to set a subwindow's size to a width of 800 pixels, and a height of 600 pixels, you can use:

```
/resize #merk 800 600
```

/move works similarly, and also takes two additional arguments: the new **X** and **Y** values of the subwindow. The **X** value sets where the top left corner of the subwindow will be located from left to right, and the **Y** value sets where the top left corner of the subwindow will be located from top to bottom. An error will be shown if invalid values are used (like negative numbers, or if it would move the window to where it would no longer be visible).

This example uses the **/move** command to move the subwindow for **#merk** on **tungsten.libera.chat** to a new location 950 pixels to the right, and 500 pixels from the top:

```
/move tungsten.libera.chat #merk 950 500
```

To find out exactly how big the area that contains the subwindows is, as well as what subwindows are available, call the **/window** command with no arguments.

The **/window** command is used to manipulate the main application window, as well the subwindows "contained" in it. To move the main application window, pass **move** as the first argument to **/window**, followed by the **X** and **Y** values. To resize the window, pass **resize** as the first argument to **/window**, followed by the **width** and **height**:

```
/* Moves the main application window to the coordinates 200,200 */
/window move 200 200

/* Resizes the main window to 1024x768 */
/window resize 1024 768
```

To maximize, minimize, or restore the main application window, pass **maximize**, **minimize**, or **restore** to **/window** as the only argument, respectively.

/window can also be used to open dialogs and other types of subwindows. To open up the README, pass **readme** as the only argument to **/window**. To open up the settings dialog, pass **settings** as the only argument to **/window**. To open the [log manager](#), pass **logs** as the only argument to **/window**. To open the log manager with only logs from certain targets, pass the name of the IRC network to show only logs from that network as an argument to **/window logs**, or pass a search term to show only logs with that term in the name of the channel or private chat to **/window logs**. You can also use **/window** to open up the [hotkey](#), [ignore](#), and [plugin](#) managers:

```
/window readme /* Opens up the README */
/window settings /* Opens up the settings dialog */
/window hotkey /* Opens up the hotkey manager */
/window ignore /* Opens up the ignore manager */
/window plugin /* Opens up the plugin manager */

>window logs /* Opens up the log manager */

/* Opens up the log manager, only showing logs from the EFnet network */
>window logs EFnet

/* Opens up the log manager, only showing logs channels named #merk */
>window logs #merk
```

/window can also arrange subwindows in common patterns. Call with **cascade** as the only argument to cascade all subwindows, and call with **tile** as the only argument to arrange all subwindows in a tiled pattern. **/window** can also be used to "move" focus to another subwindow. Call with **next** as the only argument to move focus to the "next" subwindow, and call with **previous** as the only argument to move to the "previous" subwindow.

MERK can be restarted, using the same command-line used to start the app, by passing **restart** as the only argument to **/window**.

```
/window cascade /* Cascades all subwindows */

>window tile /* Tiles all subwindows */

>window next /* Moves focus to the "next" subwindow */

>window previous /* Moves focus to the "previous" subwindow */

>window restart /* Restarts MERK with the same command-line used to start it */
```

The order subwindows are ordered in can be set in the "Settings" dialog, or by changing the **subwindow_order** setting with the **/config** command. Valid values are **creation** (the default; the order subwindows were created in), **stacking** (the "visual" order the subwindows are in), and **activation** (the order subwindows have been activated in).

/ignore

The **/ignore** command hides chat from a given nickname or user. However, messages from an **/ignored** user are still received and logged, they are just not displayed. That user's chat is hidden from **all** chat displays, no matter what server they are on. You can pass a nickname (which will hide all chat from any user with that nickname) or a hostmask (which will hide chat from only users with that hostmask) to the **/ignore** command. The **/ignore** list is saved to the configuration file, and will be applied universally until the user is **/unignored**. The **/ignore** list *cannot* be edited by the **/config** command; the only way to unignore a user is either through the right click userlist menu, the **/unignore** command, or the ignore list manager.

The **/ignore** command can also be used with wildcards. Use ***** to substitute for any number of characters, and **?** to substitute for a single character. Users **/ignored** in this way *must* be **/unignored** with the **/unignore** command, or the ignore manager. Right clicking on an ignored user in the userlist will not give an option to unignore the user. To show the user's messages again, either call **/unignore** with the specific entry used to ignore them as an argument (so, **/unignore *annoying.com*** in the example above), call **/unignore *** to clear the ignore list, or remove the entry from the ignore list with the ignore manager.

Call **/ignore** with no arguments to see the ignored user list in full. Attempting to add an entry to the ignore list that already exists will result in an error.

Entries in the ignore list can be added, removed, or edited with the GUI ignore manager, by selecting "Ignores" in the "Tools" menu.

/config

The **/config** command allows users to edit the main MERK configuration file, **settings.json**, from within the client. **Warning!** It is possible to break or otherwise "mess up" MERK's configuration with this command. If this occurs, see [**Resetting MERK to Default Settings**](#) to undo the damage.

If called with no arguments, **/config** will list all the settings that can be edited with the command. To search settings, pass search terms to the command as an argument. For example, to search all settings that have the word "windowbar" in them, you could execute **/config windowbar**; this will print a list of all the settings that match the search term:

A screenshot of a terminal window titled "irc.foonet.com" with the tab "TCP/IP". The window shows the output of a command search. At the top, it says "Found 18 config settings containing \"windowbar\"". Below this is a list of 18 items, each starting with "[07:41:03]". Each item shows a setting name followed by its value and type. The settings listed are: 1) windowbar_unread_message_animation_length = "1000" (integer), 2) windowbar_show_unread_messages = "True" (boolean), 3) windowbar_include_log_manager = "False" (boolean), 4) windowbar_bold_on_hover = "True" (boolean), 5) windowbar_underline_active_window = "True" (boolean), 6) windowbar_include_channel_lists = "False" (boolean), 7) show_windowbar = "True" (boolean), 8) windowbar_on_top = "True" (boolean), 9) windowbar_include_servers = "True" (boolean), 10) windowbar_justify = "center" (string), 11) windowbar_can_float = "False" (boolean), 12) windowbar_show_icons = "False" (boolean), 13) windowbar_doubleclick_to_maximize = "True" (boolean), 14) windowbar_include_editors = "True" (boolean), 15) always_show_current_first_in_windowbar = "False" (boolean), 16) show_windowbar_context_menu = "True" (boolean), 17) windowbar_include_channels = "True" (boolean), 18) windowbar_include_private = "True" (boolean). At the bottom of the list, it says "End 18 config search results".

A search with **/config** for settings containing "windowbar"

Each listing contains the name of the setting, what the setting's value currently is, and what type of variable the setting is. To change a setting, pass the name of the setting as the first argument to **/config**, followed by the new setting value. The new value will be checked to make sure it's valid, and if so, stored as the new setting's value. For example, to change the **show_windowbar** setting to "False", you could execute:

```
/config show_windowbar false
```

If a setting's value is a string, all arguments after the setting will be assumed to be part of the new value. For example, if using **/config** to change the default "away" message to "I'm busy right now!", you could execute:

```
/config default_away_message I'm busy right now!
```

Values are sanity checked⁸ to make sure that they are the correct type. For example, if a value is intended to be a boolean (a "true" or "false" value), **/config** will not allow that setting to be set to an integer or a string.

/config can also be used to import and export configuration files. To export the current configuration file, pass **export** as the first argument to **/config**, followed by the filename to export the configuration to; if no filename is passed, the user will be prompted for a filename. To import a configuration file, pass **import** as the first argument to **/config**, followed by the filename of the configuration file to import; if no filename is passed, the user will be prompted for a file to import. After importing a configuration file, MERK should be restarted as soon as possible.

Not all settings can be edited with the **/config** command. The internal custom dictionary for the spellchecker, hotkeys, the application font, the "ignore" list, and the option to save *all* messages to the log cannot be edited with this command, due to the possibility of breaking MERK with badly formatted data. Most of these settings can be changed with the "Settings", "Hotkey", or "Ignores" dialogs. These settings will not be searchable or settable with **/config**, nor can they be viewed with **/config**.

A full list of all settings that can be changed with **/config**, along with their default values, can be found [at the end of this document](#).

MERK should be restarted after changing settings with /config. Although many settings are applied instantly, some settings will only be applied after restarting. MERK can be restarted from scripts or as a command with /window restart.

/user

/user works exactly the same way as **/config**, only it edits the user configuration file. For most settings, this just changes default values. However, for **finger** and **userinfo**, this setting changes the values sent when MERK receives a CTCP FINGER or USERINFO request, respectively.

To set a value to a blank string, pass * as the value to set.

Here's some example uses of **/user**:

```
/* This sets the default nickname */
/user nickname new_nickname

/* This sets the default username */
/user username new_nickname

/* This sets the CTCP FINGER response */
/user finger Hey! Stop pointing at me!

/* This clears the CTCP USERINFO response */
/user userinfo *
```

⁸ ...a simple check to see if the produced material is rational (that the material's creator was thinking rationally, applying sanity). [Wikipedia](#)

/connect, /connectssl, /xconnect, and xconnectssl

These commands are used to connect MERK to IRC servers:

- **/connect** connects to an IRC server, and does *not* execute any existing connection scripts
- **/connectssl** connects to an IRC server via SSL/TLS, and does *not* execute any existing connection scripts
- **/xconnect** connects to an IRC server, and executes any existing connection scripts
- **/xconnectssl** connects to an IRC server via SSL/TLS, and executes any existing connection scripts

Pass the hostname or IP address of the server as the first argument to these commands, and the port number to connect to as the second argument. These commands can be issued from the text input widget or from scripts. Please see [Connecting to Servers](#) for an example connection script that uses these commands. Call any of these commands without arguments to open the connection dialog.

These commands will not automatically reconnect on disconnection. To ensure that MERK reconnects to the server on disconnection, add **re** before connect in all of these commands:

- **/reconnect** connects to an IRC server, and does *not* execute any existing connection scripts, automatically reconnecting on disconnection
- **/reconnectssl** connects to an IRC server via SSL/TLS, and does *not* execute any existing connection scripts, automatically reconnecting on disconnection
- **/xreconnect** connects to an IRC server, and executes any existing connection scripts, automatically reconnecting on disconnection
- **/xreconnectssl** connects to an IRC server via SSL/TLS, and executes any existing connection scripts, automatically reconnecting on disconnection

/quit and /quitall

These commands are used to disconnect MERK from an IRC server. The **/quit** command disconnects from the IRC server associated with the [context](#) the command was issued in. It can be issued without an argument, or with a "quit" message as all arguments to the command; this will be used instead of the default "quit" message.

The **/quitall** works exactly the same way as **/quit**, only it will disconnect from *all* servers that MERK is currently connected to.

```
/* This will disconnect from the IRC server associated
   with the context the command is issued in. It will
   use "See you later!" as the "quit" message. */
/quit See you later!

/* This will disconnect from *all* connected servers with
   the same message used in the last example. */
/quitall See you later!
```

/shell

The **/shell** command allows a script, or command, to execute an external process and store any output in an alias. The first argument to the command is the alias to store the output in, and all other arguments are executed as an external process.

For example, let's use **/shell** to write a script that calls the [fortune](#) Linux/UNIX program to display a fortune-cookie-like "fortune". We're going to call **fortune** with the **-s** command-line flag to generate a short fortune, store it in an alias named **FORTUNE**, and then send it as a message to the current chat:

```
restrict channel private
/shell FORTUNE fortune -s
/msg $_WINDOW Here's a fortune: $FORTUNE
```

This script:

1. Restricts the script's execution to channel and private chat windows, as it sends a message to the current window, which won't work in server window contexts.
2. Executes **/shell**, which calls **fortune -s** and stores the output in **FORTUNE**.
3. Sends a message to the current chat window containing the fortune.

/reclaim

The **/reclaim** command can be used to "reclaim" a nickname currently in use by another user. When used, MERK will periodically try to change the nickname to the desired nickname until the desired nickname is "claimed" by the client. By default, MERK will attempt to change the nickname every 30 seconds; this can be changed by [using /config](#) to change the **reclaim_nickname_frequency** setting to the desired number of seconds.

/delay

The **/delay** command is used to delay a command's execution for a set amount of time. Pass the number of seconds to delay the execution of the command as the first argument, and all other arguments will be used as the command to execute. For example, to wait 5 minutes (which is 300 seconds) before changing your nick to **merk_user**, you could use:

```
/delay 300 /nick merk_user
```

The command to be executed with **/delay** cannot contain any script-only commands, even *in scripts*. The command will fail with a "no command found" error.

/macro

The **/macro** command allows users to create their own "commands"; it creates a named command, just like MERK's other commands, that executes a script, passing any arguments to the script. Arguments to the **/macro** command are tokenized like [arguments passed to scripts](#), so if you have an argument that contains whitespace in it, contain it in quotes.

Macro names, much like aliases, cannot contain punctuation (with the exception of the underscore, `_`). They also cannot have the same name as existing commands.

As an example, we're going to create a macro named **/hello**. First, we'll write the script the macro will execute. Our macro will take one argument, a name, and send a message containing a greeting to that name to the current context. Any and all script commands can be used, including script-only commands:

```
restrict channel private
usage 1 /hello NAME
/msg $WINDOW Hello, $_1!
```

Save this script to a file named **hello.merk** in MERK's "scripts" folder. Now that our script exists, we can create the macro for our command:

```
/macro hello hello.merk
```

Now, we can use our macro! To send a greeting to a user named "bob", just enter:

```
/hello bob
```

Thanks to the **usage** script-only command, if we call our macro with less arguments than we need, the script's usage text will be displayed. And thanks to the **restrict** script-only command, if this macro is called from a server window, the macro will not execute and an error will be displayed.

Arguments to macros are tokenized (and treated) just like [arguments to scripts](#). In the example above, the command **/hello bob** is treated exactly like the command **/script hello.merk bob** was called. If you wanted to send a greeting to a user that contains spaces in the "name" argument, use quotes to contain the argument; for example, to send a greeting to "Bob the Builder", you could use the **/hello** macro like:

```
/hello "Bob the Builder"
```

Macros are not saved by MERK, so they must be recreated every time MERK is started. An easy way to make sure that the macros you use are always available is to create them in your connection scripts.

The **/macro** command can take two optional arguments; these arguments set the text that is displayed in the command list displayed by the **/help** command. The first optional argument sets the usage text (displayed in the left hand column of the **/help** display), and the second optional argument sets the command description (displayed in the right hand column of the **/help** display). To modify the previous example to use the usage and help arguments, we could create the macro with:

```
/macro hello hello.merk "/hello NAME" "Says hello to another user"
```

This adds our usage and help information to the **/help** display:

/focus [SERVER] [WINDOW]	sets focus on a subwindow
/fullscreen	Toggles full screen mode
/hello NAME	Says hello to another user
/help [COMMAND]	Displays command usage info
/hide [SERVER] [WINDOW]	Hides a subwindow

It is not possible to pass the help text to the **/macro** command without passing the usage text first; while both arguments are optional, and usage text may be passed *without* help text, if help text is desired, usage text *must* be passed as an argument first. If both usage and help text arguments are omitted, the macro is still added to the **/help** display; usage is set to the name of the macro, and the help text is set to "Executes script ", with the name of the script the macro executes.

Macros *cannot* have the same name as existing commands. Macro names must also start with a letter, and not a number or other symbol. Multiple macros *cannot* have the same name; a new macro with the same name as an existing macro will "overwrite" the older macro.

Macros are treated like commands in a lot of respects. If autocomplete for commands is turned on, autocomplete will work for macros. Macros are added to the list of commands that displays when the **/help** is used, and macros will be highlighted just like commands in the text input widget. If scripting is turned off in settings, the **/macro** command will be disabled.

Call **/macro** with no arguments to see a list of currently defined macros.

/bind and /unbind

The **/bind** command allows users to create their own hotkeys for MERK. The first argument to **/bind** should be the key sequence that triggers the hotkey; it should contain no spaces. Valid key signifiers include "Ctrl" (for the control key), "Shift" (for the shift key), "Alt" (for the alt key), and "Meta" (for the meta key). For example, the sequence "Ctrl+M" will trigger if the control key and the letter "M" are pressed at the same time. Capitalization does not matter (so "Ctrl+M" is the same bind as "ctrl+m" or "Ctrl+m").

All other arguments after the first are the command to execute when the key sequence is pressed. The command will be executed in the [context](#) of whatever window is active when the sequence is pressed. So, to print the words "Hello world" to the current window with the control key and the letter "H" are pressed, you could use:

```
/bind Ctrl+H /print Hello world
```

Only a single command can be assigned to a bind; if the desired action is complex or contains more than one command, use the **/script** command.

Commands triggered by a bound hotkey are treated *exactly* as if the command was typed into the window's text input widget and the return key was pressed. That means that they can execute any command that can be entered into the text input widget, and can *not* use any script-only commands. If the bound command does not contain any actual command, the hotkey will not do anything, and an error message is displayed. Any [built-in aliases](#) in the command will reference the [context](#) of the window the command is being executed in.

Hotkeys only work on active subwindows. If no subwindows are open, *hotkeys will not work*.

For an example, let's create a bind that sends a greeting to the current window. It will use a built-in alias to send a message to the current channel or private chat. First, we'll create our script:

```
restrict channel private  
/msg $_WINDOW Hello!
```

Save this script to a file named **hello.merk** in your "scripts" directory. Now that we have our script, we'll create our bind:

```
/bind Ctrl+H /script hello
```

Now, no matter what channel or private chat MERK is in, every time the control key is pressed at the same time as the "H" key is pressed, the message "Hello!" will be sent to the current chat. If a server window is active when the key sequence is pressed, an error will be shown.

Key sequence binds must be saved manually. To save all active binds, pass `save` as the only argument to `/bind`. This saves all binds to the configuration file, `settings.json`; all binds in the configuration file will be loaded into MERK automatically on startup.

Only one bind for a given sequence can be active at a time. For example, if there is a bind for the "Ctrl+H" sequence, creating another bind for "Ctrl+H" will display an error.

Be aware that this command can "overwrite" default hotkeys, like "Ctrl+C" for copy and "Ctrl+V" for paste, and MERK will not prevent this. Some hotkeys can not be overwritten, and the bind will not work. If a set hotkey doesn't seem to work, try a different key sequence.

To remove an existing bind, use the `/unbind` command. Pass the key sequence of the bind to remove as the first argument; just like with the `/bind` command, capitalization doesn't matter, and the sequence should not contain spaces.

To remove all created hotkey binds, pass `*` as the only argument to `/unbind`.

To see a list of all the binds currently in effect, call `/bind` without any arguments.

Binds can also be set with MERK's GUI. To bind or remove a hotkey, or save hotkeys to the configuration file, or save all current hotkeys to the configuration file, use the "Hotkeys" menu entry in the "Tools" menu.

Scripting MERK

There are two types of scripts in MERK: connection scripts, and all other scripts. Each script runs in its own thread, and no commands are blocking⁹; each command is executed immediately after being issued, without waiting for the command's process to end or resolve.

Connection Scripts

Connection scripts are the scripts entered into the [connection dialog](#), and are intended to be executed as soon as the client connects to the server. Unlike other scripts, they are stored in the user configuration file, and, outside of connection, can only be executed with the script editor. Connection scripts have the context of the associated server window created when connection begins (see [Context](#) and [Writing Connection Scripts](#)).

All Other Scripts

All other scripts are, well, *scripts*: a list of commands, one per line, issued in order. Scripts have a context, which is the window that they are called from or executed in. They can be executed in several ways:

- From the "Run" button on a server window's toolbar. The script will be executed in the server window's context.
- From the "Run" entry in a window's input menu. The text in the text input widget will be replaced with a call to the **/script** command to execute the selected file.
- From the "Run" entry in a window's chat display right-click menu. The text in the text input widget will be replaced with a call to the **/script** command to execute the selected file.
- By issuing the **/script** command. The script will be executed in the window that the command was called from's context.
- From the "Run" menu in a script editor window. The user can select which context to run the script in, or optionally select to run the script on *all* windows simultaneously (with each window running that script in the window's context).

When using the **/script** command, scripts are searched for as outlined in [Directories and Configuration Files](#); if the script can be found in this directory search, the path to that script can be omitted. For example, if a script named **example.merk** is in the **/scripts** directory, calling **/script example.merk** will execute that script. If the file extension to the script is **.merk**, than the file extension can be omitted; **/script example** will also execute the script in the previous example.

Scripts can have comments. Comments must begin with **/*** and end with ***/**, and can span multiple lines. Commands issued within comment blocks will be ignored, as will any text inside the comment block. For single line comments, the **/rem** command can be used; the command does nothing, and any arguments to it are ignored.

⁹ ... a process that is blocked is waiting for some event, such as a resource becoming available or the completion of an I/O operation. [Wikipedia](#)

Errors

For the most part, MERK handles script errors in two ways. Errors in [script-only commands](#) will prevent execution, while errors in other commands will halt the script execution when the error is encountered. If any of the following script-only command errors or conditions are detected, ***the script will not execute***:

- Calling **wait** with a non-number argument
- Calling **usage** with the wrong number of arguments
- Calling **usage** with a non-number as the first argument
- Calling **restrict** with the wrong number of arguments
- Calling **restrict** with an argument that is not server, channel, or private
- Calling **only** with no arguments
- Calling **end** with any arguments
- Calling **insert** no arguments
- Calling **insert** with a file that cannot be found, doesn't exist, or can't be read. Errors of this type will *not* display the filename the faulty **insert** call was in.
- Calling **context** with a context that doesn't exist
- Executing a script in a context that is not allowed by **restrict**
- Executing a script in a context that is not allowed by **only**
- Executing a script in a context that is not allowed by **exclude**

Every other command error will display an error message (if script error messages are turned on in settings), and halt execution of the script. Error messages will be displayed for:

- Lines that do not contain a command
- Lines that start with / and are not followed by a valid command
- Calls to commands with an incorrect number of arguments
- Calls to commands with invalid arguments
- Scripts being executed in the "wrong" context
- Errors in command execution
- Using **goto** to "jump" to a line that contains a script-only command

If an error is encountered, an error message will be displayed. The error message will contain:

- **The line number the error occurred on.** On files that contain the **insert** command, the line number may not be accurate, as the script will include the **inserted** file. Comments are stripped from scripts before execution, which may also result in inaccurate line numbers in error reports.
- **The name of the file the error is located in.** If the error is in a connection script, the filename displayed will be **SERVER:PORT** for the server's connection script. If the filename is not known or does not exist, the filename will be set to **script**. Errors in calling the **insert** command will *not* contain the filename the error occurred in, only what the erroneous call was.
- **A description of the error.**

Context

A script or command's *context* is a reference to the window the script or command is being executed in. Context is, for the most part, only necessary for scripts; the context for any commands issued by a window's text input widget is the window the command is being issued in.

Some commands can ignore an argument if they are for the current context; for example, when issuing the **/part** command, you can ignore the **CHANNEL** argument if the command is intended to be executed in the current window's context:

```
/* This leaves the current channel */
/part

/* This invites a user to the current channel */
/invite my_friend

/* This kicks a user from the current channel */
/kick my_enemy

/* This gives a user operator status in the current channel */
/mode +o my_friend

/* This sets the topic in the current channel */
/topic Welcome to my channel!
```

Context-less commands should *not* be issued by scripts, as it can get confusing if you run the script in the wrong context. However, if the script is being ran in any window's context, context-less commands are available to the script.

When running a script from a window, either through the server window's toolbar, or the input menu, the script is always ran in that window's context. The script editor "Run" menu allows you to choose which context to run the script in. If MERK is connected to more than one server, and in more than one channel or private chat on each server, the "Run" menu will give options to run the script in all of each context; for example, you can run a script in all connected channels.

An example "Run" menu from the script editor. The client is connected to a server on **localhost:6667**, and is in the channel **#merk** while having a private chat with **other_user**. Each selection will run the script in the specified context.

A window's context is "connected" to any other window contexts that share the same network stream. Commands issued from the text input widget in server or chat windows can only effect other windows that share the same server connection. This is called a "shared context".

For example, let's assume that MERK is connected to two servers, `irc.example.com` and `irc.other.net`. On `irc.example.com`, MERK is connected to two channels, `#merk` and `#python`. On `irc.other.net`, MERK is connected to the channel `#qt`. In this example, `#merk` and `#python` have a shared context, while `#qt` doesn't have a shared context with the other two window. Commands issued in `#qt` will not be able to have an effect on `#merk` or `#python`, and vice versa.

Scripts can use the **context** command to "move" the script to another context. The **context** command will search for all windows, no matter what context. The order **context** looks for windows is:

1. Windows that have a shared context with the context the script was executed in.
2. Windows from all contexts.
3. Server windows.

context will move to the *first* window it finds with the name passed to it. If you are in multiple channels with the same name, this may be problematic.

If a script is intended to only be ran in a specific type of context, the **restrict** command can be used, in one of three ways:

- **restrict server** – The script will only run in server windows or connection scripts
- **restrict channel** – The script will only run in channel windows
- **restrict private** – The script will only run in private chat windows

A script that has been "restricted" will *only* run in the context specified, and will not execute and show an error if it is ran in another context. Up to two contexts can be passed to **restrict**. For example, to make sure that a script is ran *only* in chat windows, use **restrict channel private**.

Outside of scripts, it *is* possible to "move" to another window's context via commands. The [/show command](#) can move to the context of any other window, as can the **/focus** command.

Aliases

Aliases are tokens that can be created to insert specific strings into your input in the client (if the "Interpolate aliases into input" setting is turned on, which is the default) or into your scripts. They function kind of like variables¹⁰ do in programming languages. As an example, let's create an alias named 'GREETING', and set it to the value 'Hello world!':

```
/alias GREETING Hello world!
```

Now, if you want to insert the string "Hello world!" into a command or any output, you can use the alias interpolation symbol, which is \$ by default, followed by the alias's name, to insert your alias into the command or output:

```
/msg #mychannel ${GREETING}
```

This sends a message to `#mychannel` that says "Hello world!" to everyone in the channel!

Alias names *must* start with a letter, and not a number or other symbol. This is to prevent overwriting built-in aliases created for each window's context (see [Built-In Aliases](#)). Alias names also cannot contain punctuation, except for underscores.

To create an alias, use the `/alias` command. To see a list of all aliases set for the current window, issue the `/alias` command with no arguments. To delete an alias, issue the `/unalias` command.

Aliases can also be used as macros, and can contain an entire command. For example, let's say that you like to issue a greeting to everyone that enters a channel, but typing `/msg #mychannel Hello, and welcome!` is a pain to type every time someone joins, you could create this alias:

```
/alias GREETING /msg ${_WINDOW} Hello, and welcome!
```

Now, whenever someone joins your channel, just type `$GREETING` into the text input widget to send your message! The above example uses a built-in alias, which is explained in [Built-In Aliases](#).

All aliases are *global* in scope; that is, they are available to all and every script executed on the client after they are created. They can also be changed by any script or command. Aliases created by connection scripts will be available and visible to any scripts executed after the connection script (including other connection scripts). Any script can also delete an alias with the `/unalias` command.

Built-in aliases cannot be deleted with the `/unalias` command. The client will display an error that says the alias doesn't exist if attempted.

10 [https://en.wikipedia.org/wiki/Variable_\(computer_science\)](https://en.wikipedia.org/wiki/Variable_(computer_science))

Built-In Aliases

Each window has a number of aliases for use that are built-in to the window's context, and do not require the user to create them. Built-in alias names start with an underscore (_) and are all uppercase. Some built-in aliases (see [Script Arguments](#)) are only created in certain circumstances; these have a gray background.

Alias	Value
<code>_0, _1, ...</code>	Any arguments that have been passed to the currently running script; the first argument will be set to <code>\$_1</code> , the second argument will be set to <code>\$_2</code> , and so on. <code>\$_0</code> will contain all arguments, separated by spaces; if no arguments have been passed, <code>\$_0</code> will be set to <code>none</code> .
<code>_ARGS</code>	The number of arguments passed to a script. If no arguments have been passed to the script, this will be set to <code>0</code> .
<code>_CLIENT</code>	The name of the IRC client, MERK.
<code>_CONNECTION</code>	If the connection type of the server the window is connected to; if connected via SSL/TLS, this will be set to <code>SSL/TLS</code> , otherwise it will be set to <code>TCP/IP</code> .
<code>_COUNT</code>	The number of users in the current channel. For server and private chat windows, this will be set to <code>0</code> .
<code>_CUPTIME</code>	The number of seconds that MERK has been running.
<code>_HOST</code>	The reported hostname of the server the window is connected to; if that is not known, then this will be set to the server's address, a colon, and the server's port.
<code>_DATE</code>	The current date, in "MM/DD/YYYY" format.
<code>_DAY</code>	The current day of the week.
<code>_EDATE</code>	The current date, in "DD/MM/YYYY" format.
<code>_EPOCH</code>	The current time in UNIX epoch format.
<code>_FILE</code>	The full filename of the currently running script. If called from an <code>/inserted</code> file, this will contain the name of the script being executed, not the <code>/inserted</code> file. If the current script does not have a filename, this will be set to <code>script</code> .
<code>_HCHANNELS</code>	The number of hidden channels on the server the window is connected to. If this is not known, this will be set to <code>0</code> .
<code>_MODE</code>	Any modes set on the user associated with the window. If no modes are set, this will be set to <code>none</code> .
<code>_MONTH</code>	The name of the current month.
<code>_NETWORK</code>	The network the server the window is connected to is on; if this is not known, this will be set to <code>unknown</code> .
<code>_NICKNAME</code>	The user's current nickname.
<code>_ORDINAL</code>	The current day of the month.
<code>_PORT</code>	The port on the server the window is connected to.
<code>_PRESENT</code>	If the window the alias is being used in is a channel window, this will contain a list of users in that channel, separated by commas. If there are no users in the channel, or if this is used in a non-channel context, this will be set to <code>none</code> .
<code>_REALNAME</code>	The user's realname, as set in user settings.
<code>_RELEASE</code>	The URL for the current latest release of MERK, as known at the release of the running version.

Alias	Value
_RVERSION	The current release version of MERK, as known at the release of the running version.
_SCHANNELS	The number of visible channels on the server the window is connected to. If this is not known, this will be set to 0 .
_SCOUNT	The number of visible users on the server the window is connected to. If this is not known, this will be set to 0 .
_SCRIPT	The name of the file, without the full path, of the currently running script. Only present in scripts that have been executed with the /script command. If called from an /inserted file, this will contain the name of the script being executed, not the /inserted file. If the current script does not have a filename, this will be set to script .
_SERVER	The server the window is connected to; this will be the address used to connect to the server, not the server's reported hostname.
_SOFTWARE	The server software the server the window is connected to is using. If this is not known, this will be set to unknown .
_SOURCE	The URL to MERK's source code.
_STAMP	The current time, following the format setting for timestamps.
_STATUS	If the window is associated with a channel, this will contain the window's channel status (operator , voiced , etc.); otherwise, this will be set to normal .
_SUPTIME	How long, in seconds, the client has been connected to the server associated with the current window.
_TIME	The current time, in 24-hour format.
_TOPIC	If the window the alias is being used in is a channel window, this will contain the channel's topic, if there is one. If the channel does not have a topic, or if the window is not a channel, this will be set to No topic .
_UPTIME	How long the window the script is being ran in has been connected or has been in use, in seconds.
_VERSION	The current version of MERK in use.
_USERNAME	The user's username, as set in user settings.
_WINDOW	The name of the window the script is being used in.
_WTYPE	The type of window the alias is being used in; either server for server windows, channel for channel windows, or private for private chat windows.
_YEAR	The current year.

Built-in aliases can be very useful in scripts, where the script may not "know" what [context](#) it is running in:

```
/* This sends a message to the current channel */
/msg $_WINDOW Hello, everybody! My name is $_NICKNAME

/* This sets the current channel's topic */
/topic $_WINDOW We've been around for $_UPTIME seconds!
```

They can also be used to display information about the client:

```
/* This sets the default away message */
/config default_away_message $_CLIENT $_VERSION - I'm away right now
```

Script Arguments

Arguments can be passed to a script with the **/script** command; just pass them as arguments to the command following the script file name. The **/script** command is the *only* way to pass arguments to a script.

Script arguments are tokenized¹¹ differently than arguments for commands. In arguments for most commands, arguments are considered to consist of either a single word, with no spaces, or a number of words separated by spaces. A channel name, for example, or a nickname may be an argument; the **/msg** command looks for a channel or nickname as the first argument, with all other arguments being the message to be sent. Arguments to scripts can contain spaces, and the number of arguments is important. To use an argument with spaces in it, contain the argument with quotation marks.

```
/* This calls a script with a single argument */
/script myscript.merk "Hello, world!"

/* Here are multiple arguments, with spaces in each */
/script test.merk "First argument!" "Second argument!" "And third!"
```

To access these arguments, a built-in alias is created for each one, and another is created for all arguments. Each built-in alias is named with the number of the argument: **\$_1** for the first argument, **\$_2** for the second, **\$_3** for the third, and so on. The built-in alias **\$_0** contains all arguments passed to the script, joined by single spaces; if no arguments have been passed to the script, **\$_0** will contain the string **none**.

To make sure your script is called with the right number of arguments, use the **usage** command. As the first argument to **usage**, pass the number of arguments your script requires. All arguments after this first will be displayed as the error message if your script is called with an improper number of arguments.

As an example, let's write a script that sends a greeting to someone in the current chat. Our script will require a single argument, a name. When executed with the right number of arguments, it will send the greeting to chat, and if executed with too few arguments, will tell the user how to use the script. Open the script editor, and paste the following code into it, saving the file as **greet.merk**.

```
/*
    This script requires a single argument.
    If none or more than one argument is passed,
    display script usage information.
*/
usage 1 Usage: /script $_SCRIPT NAME

/msg $_WINDOW Hello there, $_1! Nice to see you!
```

11 https://en.wikipedia.org/wiki/Lexical_analysis#Tokenization

Let's execute our script! In the text input widget, type the following and hit enter:

```
/script greet other_user
```

Our greeting is sent to the current chat:

```
wraithnix Hello there, other_user! Nice to see you!
```

If we executed our script with no arguments, an error message is displayed:

```
Usage: /script greet.merk NAME
```

Connection scripts are *never* called with any arguments. Scripts executed by any way other than the **/script** command are *never* called with any arguments.

Several built-in aliases are created for scripts. **\$_FILE** contains the full filename of the script (including path) being called, **\$_SCRIPT** contains the filename of the script without the path, and **\$_ARGS** contains the number of arguments the script was called with. The example above has a use of the **\$_SCRIPT** built-in alias. If a script is executed from the editor (and thus doesn't have a filename), both **\$_FILE** and **\$_SCRIPT** will be set to **script**.

Scripts executed with the "Run" menu in the editor are *never* called with any arguments, and will only have the **\$_SCRIPT** or **\$_FILE** built-in aliases if the script has been saved to or loaded from a filename. Scripts executed with the "Run script" button on server window toolbars will have the **\$_SCRIPT** and **\$_FILE** built-in aliases, but as they are *never* called with arguments, will have the **\$_ARGS** built-in alias set to **none**.

Argument built-in aliases can be used with **inserted** scripts, but they will always reference the script that is being executed, not the **inserted** script. For example, if an **inserted** script includes the built-in alias **\$_1**, that alias will interpolate to the first argument that was passed to the script that is being executed, *not* the **inserted** file.

Writing Connection Scripts

Connection scripts are the scripts that can be entered in the connection dialog, and are executed as soon as the client completes connecting to a server. A connection script's context is the server window created when connecting. In fact, calling **restrict server** to restrict the connection script's execution to a server window will pass successfully, while using **restrict** with any other context type will cause the connection script to not execute.

To issue commands that will have an effect on another window, use the **context** command to move the script to that window's context.

Before **contexting** to another context, be aware that that window (and the context) may "not exist" yet. The channel window may not be rendered yet, the private chat that you intended to start has not started yet, etc. The **wait** command will help you in these situations, so you can make sure that all the contexts for your script have been created before you issue commands.

For example, let's say that when you connect to your favorite server, automatically join your favorite channel, #merk, say hello, and maximize the channel window. Your connection script might look like:

```
/alias FAVORITE #merk
/join $FAVORITE
/msg $FAVORITE Hello, everybody!
wait 10
context $FAVORITE
/print $_WINDOW Maximizing $FAVORITE!
/maximize $_WINDOW
```

How long to **wait** after connection will take some trial and error, due to many factors: the speed of your Internet connection, the speed of your computer, how busy the server is, how big of a log the client is loading for display, among other things. When in doubt, a longer **wait** is preferable to a shorter one, to make sure that your script executes properly. When first writing a connection script, try **wait 30** to pause the script for 30 seconds, and tweak from there.

Example Scripts

Wave

This is a simple script that sends an emoji to the current chat, and adds a shortcut to executing the script. When executed in a channel or private chat window, it will send the "wave" emoji to the current chat. It also creates an alias, allowing the user to type **\$wave** to send the wave emoji.

```
/*
  Wave Script
  By Dan Hetrick
*/

restrict channel private
/msg $_WINDOW :wave:
/alias wave /script $_FILE
```

What this script does specifically:

1. Restrict the scripts execution to channel and private chat windows.
2. Sends the "wave" emoji to the current chat
3. Creates an alias named "wave" that will re-execute the script

Greeting

This script sends a greeting to the as a private message to a user. It takes a single argument, the username of the person the greeting is being sent to.

```
/*
 Greeting Script
 By Dan Hetrick
 */

usage 1 Usage: /script $_SCRIPT nickname
/msg $_1 Hello! Nice to see you!
```

What this script does specifically:

1. Makes sure the script is called with a single argument
2. Sends a greeting as a private message to the user set in the single argument

To make this a little easier, we'll create a macro for our greeting script. Assuming that our greeting script was saved to a file named **greeting.merk** in MERK's "scripts" directory:

```
/macro greet greeting "/greet USER" "Sends a greeting to the current chat"
```

Now, we can call our script with a new custom "command", **/greet**. So, if we wanted to send a greeting to a user named "Bob":

```
/greet Bob
```

This would send a message to the user "Bob" that consists of "Hello! Nice to see you!".

Example Connection Script

This script should be set as a connection script. Upon connection to the server, it will log the user into **NICKSERV**, join a channel the user owns, tell **CHANSERV** to give them operator status in the channel, set the channel topic, maximize the channel's window, and send a greeting to the channel

```
/*
    Example Server Connection Script
*/

restrict server
alias USERNAME my_username
alias PASSWORD my_password
alias CHANNEL #my_channel
alias TOPIC Welcome to my channel!
alias GREETING $_NICKNAME is here, everybody!

/msg nickserv IDENTIFY $USERNAME $PASSWORD
wait 5
/join $CHANNEL
/msg chanserv OP $CHANNEL
wait 10
context $CHANNEL
/topic $TOPIC
/maximize
wait 1
/msg $_WINDOW $GREETING
```

What this script does specifically:

1. Restrict the script's execution to server windows
2. Sets an alias for the user's **NICKSERV** username
3. Sets an alias for the user's **NICKSERV** password
4. Sets an alias for the user's channel
5. Sets an alias for the channel's topic
6. Sets an alias for the greeting to send once everything else is done
7. Logs into **NICKSERV** with the set username and password
8. Waits 5 seconds
9. Join the set channel
10. Tells **CHANSERV** to give the user operator status in the set channel
11. Waits 10 seconds
12. Switches contexts to the channel window
13. Sets the current channel's topic
14. Maximizes the current channel window
15. Waits 1 second
16. Sends the greeting to the current channel

Inserting Files

If there's data or aliases that you want to use in more than one script, the **/insert** command makes that easy. In the last example, a script was used to login to **NICKSERV**. In this example, we're going to store our login information in one script, and use it in another.

login.merk

```
/*
    NICKSERV Login
*/
alias USERNAME my_username
alias PASSWORD my_password
alias LOGIN_TO_NICKSERV /msg NICKSERV IDENTIFY $USERNAME $PASSWORD
```

Now, to login to **NICKSERV** from another script, use the **/insert** command to insert this file into the script, and issue the full command:

```
insert login.merk
$LOGIN_TO_NICKSERV
```

Once all aliases have been interpolated into the script, this will end up being the script that is executed:

```
/msg NICKSERV IDENTIFY my_username my_password
```

Showing the Local Temperature

This script will use the `/shell` command to fetch the currently temperature in a specific location. You may have to edit the call to get the temperature in your location. I live in Detroit, Michigan, in the United States of America, so that's the location I'm going to use. We're going to use the `curl` executable to get the temperature from <https://wttr.in/>.

```
restrict channel private
/shell TEMP curl.exe -s "https://wttr.in/Detroit?format=%t"
/msg $_WINDOW It's currently $TEMP here in Detroit
```

This script:

1. Restrict the script's execution to channel or private chat windows only, as it sends a message to the current window.
2. Use the `/shell` command to call `curl.exe` to fetch the current temperature, and store it in the `TEMP` alias.
3. Send a message to the current window containing the `TEMP` alias.

Connecting to Servers

Scripts can call other scripts, allowing scripts to be "chained"; that is, to execute one after the other. This script is an example of a connection script that connects to multiple servers, and executes multiple scripts.

First, let's create our initial connection script. We're going to use it upon connection to UnderNet. It will login to our X account before connecting to two other servers.

```
restrict server
/msg X@channels.undernet.org login username password
/join #merk
/xconnect palladium.libera.chat 6667
/xconnectssl irc.underworld.no 6697
```

This script:

1. Restricts the script's execution to server window contexts.
2. Sends a private message to UnderNet's user service bot, logging into an account.
3. Joins the **#merk** channel.
4. Connects to **palladium.libera.chat** on port 6667, executing any existing connection script when it connects.
5. Connects to **irc.underworld.no** via SSL/TLS, on port 6697, executing any existing connection script when it connects.

Scripts can also execute other scripts with the **/script** command.

Dice Rolling Script

This script uses the `/random` command to simulate a dice roll and send the result to the current channel. Pass the number of sides of the dice to roll as the first argument to the script; so, to roll a 20 sided die, pass **20** as the argument to the script:

```
restrict channel private
usage 1 Usage: /script $_SCRIPT NUMBER_OF_SIDES
/random roll 1 $_1
/msg $_WINDOW Rolling a $_1 sided die: $roll
```

This script:

1. Restricts the script's execution to chat window contexts.
2. Sets the usage text for the script, and makes sure that the script is called with one argument.
3. Generates a random number from 1 to the number passed as an argument to the script. If the argument is not a number, the script will stop executing and display an error. The generated random number is stored in the alias **\$roll**.
4. Sends a message to the current chat showing the random number that was generated.

In the game Dungeons & Dragons, rolling a 20 on a 20-sided die is a "critical", which usually means the roll succeeds or deals extra damage. Here's a version of the script rolls a 20-sided die, and notifies if a critical is rolled:

```
1 restrict channel private
2 /print Rolling...
3 /random roll 1 20
4 if $roll (is) 20 goto 7
5 /msg $_WINDOW Rolled a $roll
6 end
7 /msg $_WINDOW Critical! Rolled a $roll
8 end
```

This script:

1. Restricts the script's execution to chat window contexts.
2. Generates a random number from 1 to the number passed as an argument to the script. If the argument is not a number, the script will stop executing and display an error. The generated random number is stored in the alias **\$roll**.
3. Displays a message to the user
4. Checks to see if the roll was a 20, and if it was, "jumps" to line 7
5. Displays the roll to the current chat
6. Ends the script
7. This is the line our **if** "jumps" to; it displays to the current chat that the roll was a critical
8. Ends the script

Now that our dice rolling script is written, we can create a macro for our script, or bind the script to a hotkey. The following examples assume that dice rolling script is saved to a file name **roll.merk**, saved in MERK's "scripts" directory.

First, we'll create a macro. Our macro will be named "roll20", and will take no arguments:

```
/macro roll20 roll "/roll" "Rolls a 20 sided die, and shows the results"
```

Now, we've effectively created a new command, **/roll20**, that executes the dice rolling script every time it is called.

We can also create a hotkey for our script with the **/bind** command. Every time the user presses the control key and the "R" button at the same time, our dice rolling script will get executed in the current active window's context:

```
/bind Ctrl+R /script roll
```

Custom Day-of-the-Week Away Message

This script sets MERK's default away message to a custom message depending on what day of the week it is.

```
1 if $_DAY (is) Monday goto 9
2 if $_DAY (is) Tuesday goto 11
3 if $_DAY (is) Wednesday goto 13
4 if $_DAY (is) Thursday goto 15
5 if $_DAY (is) Friday goto 17
6 if $_DAY (is) Saturday goto 18
7 if $_DAY (is) Sunday goto 21
8 halt $_DAY is not a recognized day!
9 /config default_away_message I hate Mondays
10 end
11 /config default_away_message At least it's not Monday
12 end
13 /config default_away_message It's Wednesday, my dudes
14 end
15 /config default_away_message It's almost Friday...
16 end
17 /config default_away_message It's Friday!
18 end
19 /config default_away_message I love Saturday!
20 end
21 /config default_away_message It's almost Monday...
22 end
```

This script uses **if** and the built-in alias **\$_DAY** to check what day of the week it is, and sets the default away message, using **goto** and **/config**, with a special message for each individual day. If, for some reason, the name of the day of the week stored in **\$_DAY** is not recognized, the script uses the **halt** command to show an error message to the user.

"Trout" Macro

Many IRC clients have had the ability to create a "trout" command or macro: a command that takes a single nickname as an argument, and sends a CTCP action message to the current chat that says "slaps NICKNAME with a trout". Here's how you can do that in MERK!

First, we're going to write a script that takes a single argument and uses it to send a CTCP action message to the current chat. We'll save this script to a file named **trout.merk** in your scripts directory:

```
restrict channel private
usage 1 Usage: /trout NICKNAME
/me slaps $_1 with a trout
```

Now that we have our script, we'll use it to create a macro. We can put this command into the text input widget, a connection script, or another script:

```
/macro trout trout.merk "/trout NICKNAME" "Slaps someone with a trout"
```

Our "trout" macro is complete! Now, we can use our macro just like a command in the text input widget, scripts, or hotkeys. For example, to "slap" a user named "Bob", we'd use:

```
/trout Bob
```

This will sent a CTCP action message to the current chat window that says "[YOUR NICKNAME] slaps Bob with a trout".

Plugins and Plugin Development

MERK plugins are written in Python (just like MERK), and can use any libraries accessible to Python. If MERK is ran on Windows using the PyInstaller distribution, plugins are limited to the Python standard library, Qt5, and Twisted.

MERK plugins are stored in the **plugins** directory, and are loaded automatically when MERK starts. Each **.py** file in the **plugins** directory can contain one or more MERK plugin classes. To install a plugin, just copy the plugin's Python file into the **plugins** directory and restart MERK.

Introduction

All MERK plugins are classes derived from a class built into MERK named **Plugin**. To start off a plugin, this class must be imported from MERK:

```
from merk import Plugin
```

MERK plugins *must* be derived from this class. If a plugin source file does not contain a class derived from this class, an error will be displayed and the plugin will not be loaded.

This class is the only thing exported from the **merk** class by default, so a "splat" import works too:

```
from merk import *
```

Once the **Plugin** class is imported, a new class can be created that inherits from that class; this is a new MERK plugin. Here's an example plugin that doesn't really do anything but print a greeting to STDOUT when the plugin is loaded:

```
from merk import Plugin

class ExamplePlugin(Plugin):

    NAME = "Example Plugin"
    AUTHOR = "Dan Hetrick"
    VERSION = "1.0"
    SOURCE = "https://github.com/nutjob-laboratories/merk"

    def init(self):
        print("Hello world!")
```

Plugin classes contain methods that MERK triggers when certain events occur. In the example above, the **init()** method is triggered when the plugin is first loaded. This is the only event method that doesn't accept any arguments. The **init()** plugin event will only be executed once, when the plugin is initially loaded; if a plugin's **init()** event has already been executed, it will not execute again until the next time MERK starts up and loads plugins.

All other event methods accept a single argument, a dictionary containing information about the event, and objects that your plugin may need to complete tasks. For example, the **message()** event is triggered when MERK receives a message, and passes the user that sent the message, the message contents, the target the message was sent to (either a channel or a nickname), and the [MERK Window](#) that received that message in the dictionary. With this information, we can craft an event that prints all incoming messages to STDOUT:

```
def message(self, **args):
    print(f"{args['user']}: {args['message']}")
```

The [MERK Window](#) contains methods for interacting with the MERK GUI. For example, the **print()** method allows plugins to print messages directly to a window. This example **message()** event method prints whatever message was sent to the window that it was sent to:

```
def message(self, **args):
    args["window"].print(f"{args['user']} said {args['message']}")
```

The [Twisted IRC client object](#) passed to most events (and obtainable from the [MERK Window class](#)) can be used to perform, well, IRC actions, and will function normally. It is the raw, instantiated object that MERK uses to communicate with the IRC server. However, sending message done with this object will not "impact" MERK like "normal". For example, if the [.msg\(\)](#) method is called on the [Twisted IRC client object](#) to send a channel or private message, that message will *not* appear as chat inside MERK. The message will still be sent, and (hopefully) received by the target user or channel, but MERK will *not* display the message, and the message will not be written to log. Joining and parting channels will work normally, as will setting channel or user modes; if the [Twisted IRC object](#) is used to join or leave a channel, MERK will join that channel, creating or destroying subwindows as needed. This behavior may be desired, however; if a plugin is designed to work as a [bot](#), it might be tiresome to see user interactions with the bot in the client.

As IRC is a text based protocol, most arguments passed to events are [strings](#), unless otherwise noted.

Plugins can have four different attributes: **NAME**, **AUTHOR**, **VERSION**, and **SOURCE**. These are used by MERK to display information about each loaded plugin. A plugin doesn't *have* to have these attributes; if these attributes are not set in the plugin's source code, **NAME**, **AUTHOR**, and **SOURCE** will be set to "Unknown", and **VERSION** will be set to "1.0". All attributes should be strings. A plugin's **NAME** and **VERSION**, combined with a space between the attributes, needs to be unique; if multiple plugins have the same **NAME** and **VERSION** an error will be displayed and the plugin will not be loaded.

Plugins must also have at least one [event method](#). If a plugin doesn't have *any* event methods, an error will be displayed and the plugin will not be loaded.

Plugins also have a number of [built-in methods for interacting with MERK](#). These methods can be used to get information about MERK, what servers it's connected to, what chat windows are displayed, and the like.

Plugins run in the same thread¹² that MERK runs in, and thus, function calls in plugins can block¹³ or pause normal functioning of the application. Python and Qt have many options to run processes in a new or different thread to prevent this; that topic is far outside the scope of this document.

Plugins can be created, edited, loaded, and deleted with the [Plugin Manager](#). Creating or editing a plugin will open a special, modified version of the [script editor](#) made just for editing plugins. The plugin editor features syntax highlighting for Python, auto-indent, and more. Most features for MERK scripts are stripped out and are not visible. The plugin editor, however, can open and edit any Python file.

12 ...a *thread of execution* is the smallest sequence of programmed instructions that can be managed independently by a scheduler. [Wikipedia](#)

13 ...a process that is blocked is waiting for some event. [Wikipedia](#)

MERK Window Class

The MERK Window class is passed as an argument to many [Plugin](#) events; a list of MERK Window classes is also returned by the `windows()` and `all_windows()` [built-in plugin methods](#). This is an instance of a class that allows plugins to interact with a MERK subwindow (either a [channel](#), [private chat](#), or [server](#) window). This instance can be used to send IRC messages and display them in the client, execute [commands](#) on that window's [context](#), get information about the window or the chat contained in the window, or otherwise manipulate the subwindow.

Methods

action	Arguments	String (target of the message), String (the message)
	Returns	True if the message was able to be displayed in a window, False if the message was not displayed in a window
	Description	Sends an CTCP action message. This can message can be sent to any user or channel. If the target of the message (a user or channel) has an open window, the message will be displayed in that window's chat display.
alias	Arguments	String (the text to interpolate)
	Returns	String
	Description	Interpolates any existing aliases (both created and built-in) into text, and returns the result.
client	Arguments	None
	Returns	Twisted IRC client object
	Description	Returns the Twisted IRC client object associated with that window's context.
describe	Arguments	String (the message to send)
	Returns	True if successful, False if not
	Description	Uses the window to send a CTCP action message, displaying it in the chat window. Only functional in channel and private windows.
execute	Arguments	String (the command to execute)
	Returns	Nothing
	Description	Executes a command in the window's context.

hide	Arguments None Returns Nothing Description Hides the window.
max	Arguments None Returns Nothing Description Maximizes the window.
maximized	Arguments None Returns True if the window is maximized, False if not Description Determines whether a window is maximized or not.
message	Arguments String (target of the message), String (the message) Returns True if the message was able to be displayed in a window, False if the message was not displayed in a window Description Sends an IRC message. This can message can be sent to any user or channel. If the target of the message (a user or channel) has an open window, the message will be displayed in that window's chat display.
mini	Arguments None Returns Nothing Description Minimizes the window.
minimized	Arguments None Returns True if the window is minimized, False if not Description Determines whether a window is minimized or not.
move	Arguments Integer (the X-value of the new position), Integer (the Y-value of the new position) Returns True if the move was successful, False if not Description Moves a subwindow to the specified coordinates. If the move would put the window in a location where it could not be interacted with, this method will fail and return False .
name	Arguments None Returns String (the name of the window) Description Returns the name of the window. For server windows, this will be the server's hostname; for channel windows, this will be the name of the channel; and for private chat windows, this will be the nickname of the person the private chat is with.

note	Arguments	String (the message to send)
	Returns	True if successful, False if not
	Description	Uses the window to send a notice message, displaying it in the chat window. Only functional in channel and private windows.
notice	Arguments	String (target of the message), String (the message)
	Returns	True if the message was able to be displayed in a window, False if the message was not displayed in a window
	Description	Sends a notice. This can message can be sent to any user or channel. If the target of the message (a user or channel) has an open window, the message will be displayed in that window's chat display.
print	Arguments	String (the text to print)
	Returns	Nothing
	Description	Prints text to the window's chat display. HTML may be used.
resize	Arguments	Integer (the width of the window), Integer (the height of the window)
	Returns	Nothing
	Description	Resizes the window.
restore	Arguments	None
	Returns	Nothing
	Description	"Restores" the window; if the window has been minimized or maximized, this window returns to a normal state.
say	Arguments	String (the message to send)
	Returns	True if successful, False if not
	Description	Uses the window to send a message, displaying it in the chat window. Only functional in channel and private windows.
script	Arguments	String (the text of the script), List (the arguments to the script)
	Returns	Nothing
	Description	Executes a script in the window's context. The text of the script should be the script's code, not a filename; to execute a script via filename, use self.execute("/script FILENAME") .

show	Arguments	None
	Returns	Nothing
	Description	If the window is hidden, the window will be shown. Also, moves focus to the window.
topic	Arguments	None
	Returns	String or None
	Description	Returns the channel topic, if the window is a channel window. Otherwise, returns None .
type	Arguments	None
	Returns	String ("server", "private", "channel", or "unknown")
	Description	Returns "channel" if the channel is a channel window, "private" if the window is a private chat window, "server" if the window is a server window, or "unknown" if the window type is not known.
users	Arguments	None
	Returns	List or None
	Description	If the window is a channel window, returns a list of all nicknames in that channel. Otherwise, returns None .

Built-In Methods

These methods are built into every **Plugin**, and can be called from the **self** object passed to every [event](#).

all_windows

Arguments	None
Returns	List of MERK Windows
Description	Returns a list of all open subwindows. This will include server windows, channels, and private chats. Each entry in the list is a MERK Window .
Example	<pre>for w in self.windows(): name = w.name() print(f"{name}")</pre>

channel

Arguments	client Twisted IRC client object to query channel The name of the channel
Returns	MERK Window
Description	Returns the window for an channel on client . Returns None if the window is not open or can't be found.
Example	<code>channel = self.channel(client, "#merk")</code>

clients

Arguments	None
Returns	List of Twisted IRC client objects
Description	Returns a list of all active clients that MERK is connected to. Each client will be "registered" with the server; that is, each client can issue commands or be used with other built-in methods.
Example	<pre>for w in self.clients(): print(f"Server: {w.server}") print(f"Port: {w.port}")</pre>

find

Arguments	filename The name of the file to search for extension Optional. The file extension of the desired file. Defaults to None .
Returns	String (Returns None if file is not found)
Description	Searches for a file in the directory where MERK stores its configuration files, the scripts directory, and MERK's installation directory, in that order. Returns the first matching file found.
Example	<code>filename = self.find("bell", "wav")</code>

home is_away list master	<p>Arguments <code>None</code></p> <p>Returns <code>String</code></p> <p>Description Returns the path to the directory where MERK stores all its configuration files.</p> <p>Example <code>directory = self.home()</code></p> <p>Arguments <code>client</code> Twisted IRC client object to query</p> <p>Returns <code>Boolean</code></p> <p>Description Checks if MERK is set to "away" status on a specific client, and return <code>True</code> if MERK is away, and <code>False</code> if not.</p> <p>Example <code>if self.is_away(client): print("Away") else: print("Not away")</code></p> <p>Arguments <code>client</code> Twisted IRC client object to query</p> <p>Returns <code>List of Lists</code></p> <p>Description Retrieves a list of channels on the IRC server that client is connected to. If MERK has not requested or received a channel list from the server, this list will be empty; to request a fresh list from the server, consider executing the <code>/refresh</code> command. Each entry in the returned list is a list, with the following order: <code>channel name, user count, topic</code></p> <p>Example <code>for chan in self.list(client): name = chan[0] user_count = chan[1] topic = chan[2]</code></p> <p>Arguments <code>client</code> Twisted IRC client object to query</p> <p>Returns MERK Window</p> <p>Description Returns the server window associated with <code>client</code>.</p> <p>Example <code>server_window = self.master(client)</code></p>
---	---

private

Arguments	client Twisted IRC client object to query user The name of the private chat
Returns	MERK Window
Description	Returns the window for an open private chat with user on client . Returns None if the window is not open or can't be found.
Example	<code>chat = self.private(client, "user")</code>

windows

Arguments	client Twisted IRC client object to query
Returns	List of MERK Windows
Description	Returns a list of all open subwindows associated with client 's context. This will include server windows, channels, and private chats. Each entry in the list is a MERK Window .
Example	<pre>for w in self.windows(client): name = w.name() print(f"{name}")</pre>

Event Methods

These event methods are how **Plugins** "work". Each method is called every time a specific event occurs in MERK. Every **Plugin** *must* have at least one event method, or the **Plugin** will not load. Unless otherwise noted, event arguments are **Strings**.

action

Arguments	<code>window</code> MERK Window
<code>user</code>	The user that sent the message, in the format nickname@hostmask
<code>channel</code>	The target of the message, which may be a channel or the nickname in use
<code>message</code>	The message that was sent
Event	When MERK receives a CTCP action message
Description	This event is triggered when MERK receives a channel or private CTCP action message
Example	<pre>def action(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Target: {args["channel"]}") print(f"User: {args["user"]}") print(f"Message: {args["message"]}")</pre>

activate

Arguments	<code>window</code> MERK Window
Event	When a window is "activated"
Description	This event is triggered when a subwindow is "activated" (brought into focus or clicked on). This event will only trigger for server, channel, or private chat subwindows.
Example	<pre>def activate(self, **args): client = args["window"].client() name = args["window"].name() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Window: {name}")</pre>

away

Arguments	client Twisted IRC client object that triggered the event
	user The user that went away
	message The away message the user used
Event	When a user goes "away"
Description	This event is triggered when a user sets their status to "away" in the presence of the MERK client
Example	<pre>def away(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"User: {args["user"]}") print(f"Message: {args["message"]}")</pre>

back

Arguments	client Twisted IRC client object that triggered the event
	user The user that came back
Event	When a user comes "back"
Description	This event is triggered when a user sets their status to "back" in the presence of the MERK client
Example	<pre>def back(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"User: {args["user"]}")</pre>

close

Arguments	name The name of the subwindow
Event	When a subwindow closes
Description	This event is triggered whenever a chat subwindow closes.
Example	<pre>def close(self, **args): name = args["name"]</pre>

connected

Arguments	window MERK Window
Event	When MERK completes registration on an IRC server
Description	This event is triggered when MERK completes registration on an IRC server.
Example	<pre>def connected(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}")</pre>

connecting

Arguments	<code>client</code> Twisted IRC client object that triggered the event
Event	When MERK begins registration with an IRC server
Description	This event is triggered when MERK begins registration to an IRC server.
Example	<pre>def connecting(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}")</pre>

ctick

Arguments	<code>uptime</code> Integer. The number of seconds MERK has been running
Event	Once per second
Description	This event is triggered every second while MERK is running.
Example	<pre>def ctick(self, **args): print(f"Uptime: {args["uptime"].server}")</pre>

disconnect

Arguments	<code>client</code> Twisted IRC client object that triggered the event
	<code>message</code> The quit message used
Event	When MERK disconnects from an IRC server
Description	This event is triggered when MERK disconnects from an IRC server. <code>message</code> may be an empty string if a message was not provided or if the disconnection occurred before registration.
Example	<pre>def disconnect(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Quit Message: {args["message"]}")</pre>

init

Arguments	None
Event	On load
Description	This event is triggered when MERK loads the plugin, before any connections are attempted.
Example	<pre>def init(self): print("Plugin loaded\n")</pre>

invite

Arguments	client Twisted IRC client object that triggered the event user The user sent the invite channel The channel the invite it for
Event	When a channel invite is received
Description	This event is triggered when a channel invite is received from another user.
Example	<pre>def invite(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"User: {args["user"]}") print(f"Channel: {args["channel"]}")</pre>

join

Arguments	window MERK Window user The user that joined the channel channel The channel the user joined
Event	When a user joins a channel MERK is present in
Description	This event is triggered when user joins a channel that MERK is currently present in
Example	<pre>def join(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"User: {args["user"]}") print(f"Channel: {args["channel"]}")</pre>

joined

Arguments	window MERK Window channel The channel the client joined
Event	When MERK joins a channel
Description	This event is triggered when MERK joins a channel
Example	<pre>def joined(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Channel: {args["channel"]}")</pre>

kick

Arguments	<code>window</code> MERK Window
	<code>user</code> The user that issued the kick
	<code>channel</code> The channel that the kick occurred in
	<code>target</code> The user that was kicked
	<code>message</code> The kick message (if there is one)
Event	When a user is kicked
Description	This event is triggered when a user is kicked from a channel that MERK is present in.
Example	<pre>def kick(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Channel: {args["channel"]}") print(f"Kicker: {args["user"]}") print(f"Target: {args["target"]}") print(f"Message: {args["message"]}")</pre>

kicked

Arguments	<code>client</code> Twisted IRC client object that triggered the event
	<code>user</code> The user that issued the kick
	<code>channel</code> The channel that the kick occurred in
	<code>message</code> The kick message (if there is one)
Event	When MERK is kicked from a channel
Description	This event is triggered when the user is kicked from a channel.
Example	<pre>def kicked(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Channel: {args["channel"]}") print(f"Kicker: {args["user"]}") print(f"Message: {args["message"]}")</pre>

left

Arguments	<code>client</code> Twisted IRC client object that triggered the event
	<code>channel</code> The channel the client left
Event	When MERK leaves a channel
Description	This event is triggered when MERK leaves a channel
Example	<pre>def left(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Channel: {args["channel"]}")</pre>

line_in

Arguments	client Twisted IRC client object that triggered the event line The line received by the client
Event	Incoming data
Description	This event is triggered every time MERK receives a line of data from an IRC server.
Example	<pre>def line_in(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Line: {args["line"]}")</pre>

line_out

Arguments	client Twisted IRC client object that triggered the event line The line sent by the client
Event	Outgoing data
Description	This event is triggered every time MERK sends a line of data to an IRC server.
Example	<pre>def line_out(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Line: {args["line"]}")</pre>

lost

Arguments	client Twisted IRC client object that triggered the event
Event	When MERK loses connection to an IRC server
Description	This event is triggered when MERK's connection to an IRC server is lost.
Example	<pre>def lost(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}")</pre>

message

Arguments	window MERK Window
	user The user that sent the message, in the format nickname@hostmask
	channel The target of the message, which may be a channel or the nickname in use
	message The message that was sent
Event	When MERK receives a message
Description	This event is triggered when MERK receives a channel or private message
Example	<pre>def message(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Target: {args["channel"]}") print(f"User: {args["user"]}") print(f"Message: {args["message"]}")</pre>

mode

Arguments	client Twisted IRC client object that triggered the event
	user The user that set the mode. If the mode was set by the server, this will be set to "*".
	target The user the mode was set on
	mode The mode that was set
	arguments Tuple; any arguments passed to the mode.
Event	When a mode is set.
Description	This event is triggered when a user or channel mode is set.
Example	<pre>def mode(self, **arguments): client = arguments["client"] user = arguments["user"] target = arguments["target"] mode = arguments["mode"] args = arguments["arguments"]</pre>

motd

Arguments	client Twisted IRC client object that triggered the event
	text The text of the message of the day
Event	When the server sends the message of the day
Description	This event is triggered when MERK receives the MOTD from the server.
Example	<pre>def motd(self, **args): client = args["client"] print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"{args["text"]}")</pre>

nick

Arguments	client Twisted IRC client object that triggered the event nickname The new nickname
Event	Nickname change
Description	This event is triggered every the user's nickname changes. This will be triggered on connection when the user's nickname is set.
Example	<pre>def nick(self, **args): print(f"New nickname: {args["nickname"]}")</pre>

notice

Arguments	window MERK Window user The user that sent the message, in the format nickname@hostmask channel The target of the message, which may be a channel or the nickname in use message The message that was sent
Event	When MERK receives a notice
Description	This event is triggered when MERK receives a channel or private notice
Example	<pre>def notice(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"Target: {args["channel"]}") print(f"User: {args["user"]}") print(f"Message: {args["message"]}")</pre>

ping

Arguments	client Twisted IRC client object that triggered the event
Event	Whenever the server sends a ping
Description	This event is triggered when the server sends a ping to the client.
Example	<pre>def ping(self, **args): args["client"] print(f"Server: {client.server}") print(f"Port: {client.port}") print("Ping? Pong!")</pre>

part

Arguments	<code>window</code> MERK Window
	<code>user</code> The user that left the channel
	<code>channel</code> The channel the user left
Event	When a user leaves a channel MERK is present in
Description	This event is triggered when user leaves a channel that MERK is currently present in
Example	<pre>def part(self, **args): client = args["window"].client() print(f"Server: {client.server}") print(f"Port: {client.port}") print(f"User: {args["user"]}") print(f"Channel: {args["channel"]}")</pre>

quit

Arguments	<code>client</code> Twisted IRC client object that triggered the event
	<code>user</code> The user that quit
	<code>message</code> The quit message the user used
Event	When a user quits IRC in view of MERK
Description	This event is triggered when user quits IRC in a channel or private chat that MERK is in.
Example	<pre>def quit(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"User: {args["user"]}") print(f"Message: {args["message"]}")</pre>

rename

Arguments	<code>client</code> Twisted IRC client object that triggered the event
	<code>old</code> The user's old nickname
	<code>new</code> The user's new nickname
Event	When a user changes nicknames
Description	This event is triggered when a user changes a nickname. This event will <i>not</i> trigger when MERK changes nicknames.
Example	<pre>def rename(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Old nickname: {args["old"]}") print(f"New nickname: {args["new"]}")</pre>

server

Arguments	client Twisted IRC client object that triggered the event message The message
Event	When a server message is received
Description	This event is triggered if a server message is received by MERK.
Example	<pre>def server(self, **arguments): client = arguments["client"] message = arguments["message"]</pre>

subwindow

Arguments	window MERK Window
Event	When a new chat subwindow is created
Description	This event is triggered whenever MERK creates a new chat subwindow.
Example	<pre>def subwindow(self, **arguments): window = arguments["window"] print(window.name())</pre>

tick

Arguments	client Twisted IRC client object that triggered the event uptime Integer. The number of seconds the client has been connected
Event	Client uptime
Description	This event is triggered once a second, every second that MERK is connected to a server
Example	<pre>def tick(self, **args): print(f"Server: {args["client"].server}") print(f"Port: {args["client"].port}") print(f"Uptime: {args["uptime"]}")</pre>

topic

Arguments	window MERK Window user The user that set the topic channel The channel the topic was set on topic The new channel topic
Event	When a channel's topic is set.
Description	This event is triggered when a channel's topic is set
Example	<pre>def topic(self, **arguments): client = arguments["window"].client() user = arguments["user"] channel = arguments["channel"] topic = arguments["topic"]</pre>

unmode

Arguments	client Twisted IRC client object that triggered the event
	user The user that removed the mode. If the mode was set by the server, this will be set to "*".
	target The user the mode removed from
	mode The mode that was removed
	arguments Tuple; any arguments passed to the mode.
Event	When a mode is removed.
Description	This event is triggered when a user or channel mode is removed.
Example	<pre>def unmode(self, **arguments): client = arguments["client"] user = arguments["user"] target = arguments["target"] mode = arguments["mode"] args = arguments["arguments"]</pre>

Example Plugins

Away Notifications

In this example, we're going to write a plugin that notifies every chat that MERK is in whenever it sets its status to "away" or "back". To accomplish this, we're going to use the [ctick\(\) event method](#), the [is_away\(\)](#) and [windows\(\)](#) [built-in methods](#), and some [MERK Window classes](#).

Our plugin will use [ctick\(\)](#) to check every client for a status change once per second. First, we declare a class variable we'll need in [init\(\)](#): a list to store notified clients. If a client's away status has changed to either "away" or "back", our plugin will send a CTCP action message to every [open chat window](#) telling them about our status change. To prevent the plugin from spamming a status once per second, the plugin will store which [Twisted IRC clients](#) have been notified in our [list](#) class variable: when the client goes away, the [Twisted IRC object](#) is stored, and when the client comes "back", the [Twisted IRC object](#) is removed from storage.

This plugin should work with any number of server connections, and will only notify the connections that have had their status changed. This plugin also doesn't do any error checking; it calls the [MERK Window method .describe\(\)](#) on [server windows](#), which doesn't work, but it doesn't notify the user and no error will be displayed.

```
from merk import Plugin

class AwayNotify(Plugin):

    NAME = "Away Notify"
    AUTHOR = "Dan Hetrick"
    VERSION = "1.0"
    SOURCE = "https://github.com/nutjob-laboratories/merk"

    def init(self):
        self.notified = []

    def ctick(self, **args):
        uptime = args["uptime"]

        for client in self.clients():
            if self.is_away(client):
                if not client in self.notified:
                    self.notified.append(client)
                    for window in self.windows(client):
                        window.describe("is now away")
            else:
                if client in self.notified:
                    self.notified.remove(client)
                    for window in self.windows(client):
                        window.describe("is now back")
```

Visual Notification

This plugin will give the user a "visual" notification if their name is mentioned in a chat: the subwindow that their nickname was mentioned in will be put into focus, unminimizing the window if the window was minimized.

```
from merk import Plugin

class VisualNotify(Plugin):

    NAME = "Visual Notify"
    AUTHOR = "Dan Hetrick"
    VERSION = "1.0"
    SOURCE = "https://github.com/nutjob-laboratories/merk"

    def message(self, **args):
        window = args["window"]
        channel = args["channel"]
        user = args["user"]
        message = args["message"]
        client = window.client()

        if not window.type() == "server":
            if client.nickname in message:
                if window.minimized():
                    window.restore()
                window.show()
```

Advanced Settings

The last section in the "Settings" dialog shows a number of settings that can be used to fundamentally change how MERK works. **WARNING:** Changing these settings may break your installation of MERK, break any existing scripts, or fill up your hard drive. If this occurs, please see [Resetting MERK to Default Settings](#).

Changing these settings is not recommended, but may be desired.

Options

To change any of these settings, advanced settings must be enabled by clicking this checkbox:

Unchecking this checkbox will reset all the advanced settings to the value stored in the configuration file, and no settings will be saved. This *must* be enabled when clicking the "Apply" or "Apply & Restart" buttons for any changes to be saved. When changing any any advanced setting, restarting MERK is recommended.

- **Connection heartbeat.** This sets how often MERK "pings" the IRC server to keep the network connection active. The default is once every 120 seconds.
- **Max message length.** IRC has a hard limit of 512 characters for chat messages, and this must include the user's nickname and the appropriate chat command. 400 characters is the limit that MERK uses to determine if a chat message needs to be split into multiple messages.
- **Flood protection for long messages.** Chat messages that have been split up for exceeding the maximum message length will be sent once per second, to avoid triggering a server's flood protection. Turned on by default.
- **Show server pings in server windows.** MERK sends "pings" to the IRC server to keep the network connection active. Checking this box will display whenever the client receives a "ping" reply from the server.
- **Save all system messages to log.** Checking this option will save nearly all messages displayed if logging is turned on. This will drastically increase the size of saved logs.
- **Write all network input and output to STDOUT.** This will show all IRC network traffic in STDOUT, which is normally printed to the console MERK is being ran from. This will not display anything if MERK is being executed with the PyInstaller executable (without using additional software to view STDOUT).
- **Write all network input and output to a file in the user's settings directory.** This will write all network input and output to a file or files in the **settings** directory. Each IRC connection will have its input and output written to a file named **SERVER-**

PORT.txt. So, a connection to **irc.libera.chat** on port **6697** would have its input and output written to **irc.libera.chat-6697.txt**. **WARNING!** This will write a *lot* of data to your hard drive.

Settings Editable by /config

The following is a list of all settings editable with the `/config` command, along with their default values. Settings are in the format "`setting: value`". Values in quotation marks are strings, values set to `false` or `true` are boolean, and numerical values are integers. Values that appear in italics are generated when MERK is ran for the first time, and vary depending on the version of the application.

Several settings require a string value that must be specific strings:

- `qt_window_style`. *This must be set to a valid value string, depending on your installation of Qt, and will vary. Trying to set it to an invalid value will list valid values for your platform.*
- `windowbar_justify` and `menubar_justify`. *Must be "left", "right", or "center".*
- `default_spellcheck_language`. *Must be "en", "fr", "es", "de", "pt", "it", "nl", or "ru".*
- `syntax_comment_style`, `syntax_command_style`, `syntax_channel_style`, `syntax_alias_style`, `syntax_operator_style`, `syntax_nickname_style`, `syntax_emoji_style`, and `syntax_script_only_style`. *Must be strings containing only "bold" or "italic", separated by spaces.*
- `subwindow_order`. *Must be "creation", "stacking", or "activation".*
- **All settings ending in `_color`**. *Must be a valid [Qt color descriptor](#) (such as an [SVG color keyword name](#)), or an HTML hexadecimal color value (like "#FFFFFF" for white or "#000000" for black).*
- `sound_notification_file`. *Must be a string containing a valid path for a [WAV file](#). The default value is a file located in MERK's resource file.*
- `timestamp_format`. *Must be a string containing a valid [strftime](#) format.*
- `emoji_shortcode_language`. *Must be "alias", "en", "pt", "it", "fr", "de", "fa", "id", "zh", "ja", "ko", "ru", "ar", or "tr". For more information, please see the [Emoji library repository](#).*

Settings and Default Values

- alias_interpolation_symbol: "\$"
- always_scroll_to_bottom: false
